On admission, the patient appeared fairly well developed, but emaciated, seeming ten years past the stated age. The skin was sallow, and the mucous membranes were pale. The pupils were small and slightly irregular. The fundi showed arteriosclerotic changes. The tonsils were large and cryptic. A few pea-sized lymph nodes lay in the right anterior part of the neck. The breasts were atrophic. There were dullness and diminished tactile fremitus and breath sounds over the left upper lobe of the lung, anteromedially. The heart sounds were loud over this area. Posteriorly, over the right upper lobe, there was impaired resonance, with diminished tactile fremitus, breath sounds and voice sounds. The left border of the heart was

displaced 2 cm. beyond the midclavicular line; the pulmonic second sound was greater than the aortic, and the mitral first sound was loud. A systolic murmur was loudest over the pulmonary area, but could be heard well out in the axilla. The abdomen was flat and soft. A large, firm mass consistent with liver and moving with respirations extended 9 cm. below the costal margin. Traube's space was diminished. The spleen was not palpable. Vaginal and rectal examination showed the cervix displaced to the left, and the uterus fixed in retroversion. The pelvic contents seemed "bound down," and there was some question of a polypoid mass high in the rectum. The pulse was of Corrigan type, regular at 95, and faint pistol-shot sounds were audible over the femoral arteries.

The respirations were 20, and the temperature was 99.5°F. The blood pressure was 130 systolic, 55 diastolic.

Examination of the blood showed a red-cell count of 3,200,000 with 7.5 gm. hemoglobin, and a white-cell count of 15,800 with 84 per cent polymorphonuclears, 11 per cent lymphocytes and 5 per cent monocytes. The van den Bergh reaction was normal. The serum albumin was 3.7 gm. and the globulin 2.7 gm. per 100 cc. The nonprotein nitrogen was 20 mg. per 100 cc. A bromsulphalein test showed 15 per cent retention of the dye. The urine showed a ++ test for albumin, with 80 to 100 white cells, a few red blood cells and many bacteria per high-power field in the sediment. Urine culture yielded colon bacilli.

An electrocardiogram was within normal limits.

Roentgenograms of the chest showed a mass measuring 12 by 11 by 10 cm. in the posterior portion of the right upper lobe, displacing the trachea to the left (Fig. 1). The intercostal spaces in the region of the mass were slightly wider than those on the left side. Multiple round shadows were spread throughout the remainder of both lung fields. There was destruction of the medial end of the twelfth left rib. The liver shadow was large.

No therapy was instituted. The temperature gradually fell to 97°F., and the patient failed progressively. Death occurred on the tenth hospital day.

### DIFFERENTIAL DIAGNOSIS

DR. LOWREY F. DAVENPORT: We are given enough evidence to say that this patient definitely had a malignant tumor. The crux of our problem is to decide where the tumor originated, whether the tumor mass seen in the x-ray film was primary in the lung or metastatic from some other focus.

May we see the films?

DR. AUBREY O. HAMPTON: In addition to the area of destruction described in the record, the pa-

rule that epidermoid cancer invades the lymphatics, but not the blood stream?

DR. MALLORY: Yes; I think that is probably so.

DR. DAVENPORT: I shall make as my diagnosis a primary malignant tumor in the liver, probably developing on a cirrhotic background, with metastases to the lungs and with inflammation in the pelvis binding down the uterus and involving the lower gastrointestinal tract, which may or may not have been a part of the terminal picture. The transient bouts of fever and the occasional chills and night sweats go well with infection in the liver, but could occur with tumor and may have been partly due to breakdown of a tumor mass in the liver.

DR. MALLORY: Dr. Hampton, have you any further comment?

DR. HAMPTON: As one looks at the chest films, one can see that the spleen is not enlarged, and according to Dr. Richard Schatzki,\* primary carcinoma of the liver is commonly associated with advanced cirrhosis. The cases that he reported had large spleens, and varices in the esophagus. I wonder how we can explain the absence of enlargement of the spleen.

DR. EDWARD F. BLAND: Someone might wonder what I had to do with this case, but it so happens that I was visiting on the medical ward for Dr. J. H. Means, who was away. Dr. W. M. Jeffries, the senior house officer, and I took this case up in some detail, and we reasoned somewhat as Dr. Davenport did, but did not go quite so far in regard to the liver. The patient was too sick to have many special diagnostic procedures performed. The X-ray Department strongly implied that they thought this was a primary malignant lesion of the lung. We were inclined to metastatic involvement of the lungs because of the preceding gastrointestinal symptoms. I think our final diagnosis was metastatic carcinoma of the lungs, liver and bones from an undetermined focus, but probably in the gastrointestinal tract. Those of us who palpated the abdominal mass believed it to be liver with metastatic involvement.

DR. DAVENPORT: What did you think of the polyp in the rectum?

DR. BLAND: We could not identify it.

DR. F. DENNETTE ADAMS: Did anyone give thought to the pancreas?

DR. BLAND: We did not.

DR. ADAMS: The woman had diarrhea, loss of weight and digestive symptoms.

DR. HAMPTON: We have not seen metastases to the lung from either pancreas or liver with that appearance. I vote against the liver or pancreas.

\*Schatzki, R. Roentgenological diagnosis of primary carcinoma of the liver. *Am. J. Roentgenol.* 46:476-483, 1941.

A PHYSICIAN: I believe that the rectum was involved.

DR. DONALD S. KING: I should guess that the primary site was the lungs. We have one case—there is always one!—with metastasis to the contralateral lung. I do not quite see why metastases to the liver and bones and so forth, would not account for all the symptoms. I grant that it is an unusual x-ray picture.

DR. MALLORY: It is difficult to explain metastasis to the contralateral lung from bronchiogenic cancer, but such metastasis has occurred. I think it usually results from involvement of the hilar node and extension from there into the pulmonary artery, which permits seeding of the opposite lung. We occasionally see tuberculosis spread by that method, and it is possible with cancer but certainly unusual.

DR. FLETCHER H. COLBY: It still could be a lesion of the kidney. The unusual thing is the massive tumor mass, but I should still say that the patient could have had a renal-cell carcinoma.

DR. HAMPTON: That is a possibility, but the films do not look right. Lymphoma is the next thing we should consider, I think.

DR. MALLORY: Have you ever seen nodules as discrete as that with lymphoma in the lung?

DR. HAMPTON: Once; but not so many and perhaps not quite so smooth and sharp.

DR. DAVENPORT: Is it not true that one can have a tremendous tumor mass in the liver, and no demonstrable change in liver function?

DR. MALLORY: Yes; with metastatic, but not with primary, carcinoma.

DR. HAMPTON: What do you think of the absence of enlargement of the spleen?

DR. WILLIAM B. BREED: I think it depends entirely on the stage of advance of the cirrhosis.

DR. MALLORY: One can say that symptoms occur only in advanced cirrhosis.

DR. BREED: Then that is the answer to it. The patient should have had an enlarged spleen.

DR. MALLORY: I think Dr. Hampton has a strong point there.

DR. BREED: So do I.

#### CLINICAL DIAGNOSIS

Carcinoma of lung (? bronchiogenic), with metastases to lungs and liver.

#### DR. DAVENPORT'S DIAGNOSIS

Carcinoma of liver, with metastases to lungs.

## ANATOMICAL DIAGNOSES

Carcinoma of right kidney, with metastases to lungs, bronchial lymph nodes, vertebral bone marrow and left twelfth rib.  
Nephritis, suppurative, left, acute.  
Cystitis, diphtheritic, urinary bladder, acute.  
Emaciation, marked.  
Brown atrophy of organs.  
Leiomyomas of uterus.  
Arteriosclerosis, minimal of aorta.

## PATHOLOGICAL DISCUSSION

DR. MALLORY: Post-mortem examination showed that the primary tumor was a hypernephroma. The right kidney was nearly twice the normal size, and the liver was small—1600 gm.—and entirely normal. The lungs were studded with metastases; one extremely large one in the right upper lobe was immediately subpleural on the posterior surface of the lung and did not connect with any bronchus. One of the smaller metastases had invaded a bronchus and started to grow as a plug of tumor tissue up the bronchus, so that as a matter of fact if the patient had been bronchoscoped a biopsy would have proved the diagnosis without any question.

DR. HAMPTON: Which bronchus?

DR. MALLORY: It was the main bronchus of the left upper lobe.

DR. HAMPTON: I wondered about that. This wedge-shaped shadow in the left upper lobe bothered me, but I did not mention it. There is some atelectasis in that area.

DR. BLAND: I might say that the edge of the liver was 9 cm. below the costal margin, but the patient was emaciated.

DR. RICHARD CLARKE: At the time of post-mortem examination, was the liver down, or was it up at the costal margin?

DR. MALLORY: It was 2 cm. below the costal margin.

A PHYSICIAN: Can the kidney rotate the liver downward?

DR. MALLORY: I think it was the kidney that was felt. It was the right kidney that contained the tumor, and I can remember a kidney that I mistook for liver once.

DR. DAVENPORT: Only one thing bothers me. Why was the liver function so depressed?

DR. ALFRED KRANES: The only evidence of depression was the 15 per cent dye retention. The test is not extremely reliable.

DR. MALLORY: There was a somewhat low serum protein. On the other hand, the patient had a severe pyelonephritis on the other side. The right kidney was almost completely replaced by tumor, and the left kidney showed an active pyelonephritis. Accordingly, I think the kidneys could have been responsible for the low serum protein.

A PHYSICIAN: Was there a tumor in the rectum?

DR. MALLORY: There was a fibroid on the posterior surface of the uterus.

DR. COLBY: Was there anything else in the pelvis?

DR. MALLORY: Nothing.

## CASE 28192

## PRESENTATION OF CASE

*First admission.* A twenty-nine-year-old electric welder was admitted to the hospital because of recurrent masses in the groin.

Fifteen years before entry, the patient first noticed a swelling in the right groin. Ten years later, because of enlargement of this mass, a biopsy was taken in a community hospital and reported as "lymphoblastoma." Subsequently, the patient was given roentgen-ray treatments to each groin about once a year. Except for occasional slight pain over the right upper leg anteriorly, persistent swelling in the right groin remained the sole symptom until six weeks before entry, when occasional severe gnawing pain unrelated to meals appeared in the upper abdomen and radiated down to the pubis. During intervals between the attacks of pain, the abdomen was frequently sore. Concomitantly, the patient began to feel listless and tired, and lost about 7 pounds of weight. A few days before entry, he had several chills, accompanied by a fever of 104°F. The lump in the right groin showed no recent swelling, and the patient was not aware of any other masses.

The past and family histories were irrelevant.

On admission, the patient appeared well developed and nourished, with a warm dry skin. The throat was somewhat reddened. A few rather small lymph nodes were palpable in the front of the neck on each side, and a few similar nodes were felt in each groin. The heart and lungs were normal. The abdomen was tense and firm, without definite tenderness. The liver and spleen were not palpable. The extremities were normal.

The blood pressure was 115 systolic, 80 diastolic. The temperature was 101.5°F., the pulse 90 and the respirations 22.

Examination of the blood showed a white-cell count of 7400 with 69 per cent polymorphonuclears, 4 per cent large lymphocytes, 14 per cent small lymphocytes and 13 per cent monocytes. A second examination showed a white-cell count of 6900, including 73 per cent polymorphonuclears, 2 per cent small lymphocytes, 23 per cent monocytes, 1 per cent eosinophils and 1 per cent basophils. The hemoglobin varied from 14.5 to 12.4 gm. The blood Hinton reaction was negative. Agglutination tests with typhoid and brucellar antigens were

negative. A blood culture was negative. The urine and stools were normal.

Roentgenograms of the gastrointestinal tract showed a normal esophagus and stomach. There was some delay of barium in the second portion of the duodenum, and deformity of the third portion due to pressure of an ill-defined extrinsic mass. The mucosa appeared uninvolved. The lower border of the liver was rather low, but the spleen was not definitely enlarged. A roentgenogram of the chest showed no evidence of disease.

Roentgen irradiation was given for five days, in total dosage of 600 r to the right groin and 100 r to the anterior liver field, followed in six days by a course of 1200 r to the posterior lumbar region. Two days after this treatment was begun, the temperature rose to 104°F., and it ranged from 101 to 104°F. for the next two weeks. Diarrhea likewise appeared, with seven or eight soft movements a day. The patient was discharged on the twentieth hospital day.

*Final admission* (eighteen days later). The patient remained at home in bed. The temperature continued high, and he experienced occasional chills. He felt quite weak, and the diarrhea gradually subsided.

On re-entry, physical examination was essentially as before. Areas of first-degree roentgen dermatitis appeared over the epigastrium and lumbar spine.

Laboratory studies, including three negative blood cultures, were essentially as before, with the addition of a normal lumbar puncture, a negative stool culture, and a tuberculin reaction that was weakly positive in a dilution of 1:50,000.

A roentgenogram of the chest showed generalized miliary lesions, involving both lungs entirely, and seeming most like miliary tubercles. There was no evidence of pleural fluid, or of enlargement of hilar or mediastinal lymph nodes. A questionable area of localized infiltration 1.5 cm. in diameter lay in the right apex.

In the course of a month, the patient had remittent fever, the temperature varying from 101 to 104°F. and spiking each afternoon. The pulse was correspondingly high. Roentgen therapy was given to the lung fields in doses of 600 r to the left and 750 r to the right. Subsequent roentgenograms taken four and twelve days after this first examination showed a slight increase in the miliary lesions, and no change thereafter. In the second and third weeks in the hospital, abdominal fluid began to accumulate. Paracentesis yielded 2500 cc. of turbid green sterile fluid with a specific gravity of 1.010. The centrifugate showed only acute inflammatory cells, with no evident organisms or tumor cells. The patient continued to fail rapidly, dying on the thirty-first hospital day.

## DIFFERENTIAL DIAGNOSIS

DR. MYLES P. BAKER: On the first admission, the diagnostic problem was that of a patient with upper abdominal pain present for six weeks, associated with fatigue, chills and fever. The locus of the pain appears to have been just above the umbilicus, probably in the midline, and it was crampy pointing to something associated with the small intestine. There were several important features of the physical examination at the time of this admission. The first was the absence of generalized lymphadenopathy. I take it from the description that there was no massive swelling in either groin and that no large mass had been present for many years. Since x-ray examination of the chest was negative, we have no proof or evidence of mediastinal lymph-node enlargement, and there was no enlargement of the spleen. Moreover, there was x-ray evidence of an extrinsic mass, pressing on the third part of the duodenum, which might well have contributed to the upper abdominal crampy pain that had been one of his chief complaints. Finally, there was a distinctly unsatisfactory reaction to what was presumably adequate radiation therapy for a lymphomatous disorder. The blood picture is emphasized here. I can only say that the increase in monocytes is interesting but not necessarily associated with tubercle formation. It is obvious that those responsible for this man's care hoped that he had a radiosensitive lymphoma and treated him accordingly. They must have been dissatisfied with the effect of the treatment and discharged him with a distinctly poor prognosis and, I should think, with considerable doubt that the previous biopsy diagnosis of lymphoblastoma had been correct.

Against the diagnosis of lymphoma is the clinical course. It must be rare to have lymphoma localized in the groin for fifteen years—from the age of fourteen to twenty-nine. We do not know from the story whether the x-ray treatment approximately once a year effected any demonstrable decrease in the size of this solitary swelling. Presumably, it did, but there is no evidence to that effect. Lymphoma in a boy in his teens or early twenties is apt to progress without long remissions, and since this man had rather scanty treatment, I think the duration is distinctly against the diagnosis and brings up the question whether this could have been tuberculous adenitis from the start.

On the second admission, the patient returned with the same fever, in addition to positive x-ray findings in the chest, only three or four weeks after the previous negative chest plates. On this admission, along with the negative blood cultures and negative lumbar puncture, he had a weakly

positive tuberculin reaction to a relatively high dilution of tuberculin.

I should like to ask Dr. Hampton to comment on the chest x-ray films.

DR AUBREY O. HAMPTON: This series of films extends over a period of a year and seven months, and for the first seventeen months the chest was normal. At the time of entry into the hospital with fever, it shows this milary process in the lung; a very fine, diffuse, symmetrical process, without anything else—no enlargement of the lymph nodes, no areas of consolidation, no fluid and no areas of calcification. After the x-ray treatment, it appears that the chest is no better, and the milary lesions are larger. Examination of the spine, which was done on the outside, is not reported. In our films, the body of the fifth lumbar vertebra is uniformly dense. One can see bone trabeculae in it, and if the patient were not so young, I should have to say that he had Paget's disease. It is true, however, that lymphoma produces new bone formation in bones that appears somewhat like that, particularly if it has been treated.

The pressure defect in the duodenum is not very obvious in this film. It must have been more obvious to the man who fluoroscoped the patient, at any rate, there is some spasm and delay in the third portion of the duodenum as it crosses the spine. The liver shadow is rather faint in the lower portion and not very large. The spleen does not appear to be very enlarged. The hands and feet were examined, I suppose, to discover sarcoid; no abnormalities are present.

DR BAKER: What about the interpretation of the right apex during the second admission?

DR HAMPTON: I cannot be absolutely sure that the apexes are not similar to the rest of the lung. Certainly, there was nothing in the apex two months before.

DR BAKER: Could you rule out metastatic carcinoma on the basis of the x-ray films on the second admission?

DR HAMPTON: I think we have seen one case in this hospital with a fine milary process and to be metastatic carcinoma.

DR DONALD S. KING: Even that case is unproved.

DR BAKER: The question comes up, What lesions can produce this kind of milary process in the lungs? First of all, the likeliest is tuberculosis. With such a diagnosis, I think the weakly positive skin tuberculin test is consistent in a sick person.

DR ALLEN G. BRALEY: The dilution was 1:50,000.

DR BAKER: I beg your pardon. Then we shall have to say that the strongly positive tuberculin

test is going to be somewhat difficult to explain in such a sick person.

Lymphoma has been reported as giving an x-ray picture that is difficult to distinguish from milary tuberculosis. If lymphoma affects the lung parenchyma, it is much more likely to do so in the form of peribronchial infiltration or as an isolated nodule. It may be the site of cavity formation or it may take the form of pneumonia with or without atelectasis, but this would be a distinctly rare x-ray picture with lymphoma.

The other possibilities can be ruled out on the clinical story alone, such as silicosis, which usually gives coarser mottling than this. Yeast infections run a more benign course, and do not give the picture of such an acutely sick patient. One or two patients that I have seen with sarcoid, in whom the x-ray picture was consistent with milary tuberculosis, have been in much better health than this man was. I have followed one daily over a course of five years, and at no time was she at all ill, she was always ambulatory, had no symptoms except those referred to her iritis, and now, five years after the onset of the iritis, her chest is almost entirely clear. This is not true of the case under discussion. We are dealing with a man who was in his last month of life at the time when he developed this picture of milary seeding. I think we can rule out a relatively benign process such as sarcoid on that basis. We have, as Dr. Hampton said, little reason to suspect metastasis to the lungs from a retroperitoneal mass such as sarcoma.

Could this man have developed milary tuberculosis with a positive x-ray plate only six weeks after his film had been negative? That is possible, and although I cannot cite a definite case to back me up, I think that the likeliest diagnosis here is not lymphoma but tuberculous adenitis, with retroperitoneal tuberculous lymph nodes and acute hematogenous spread of infection, with a picture of milary tuberculosis at the end, and tuberculous peritonitis. The accumulation of ascitic fluid with a low specific gravity is not diagnostic and could occur in lymphoma as well as in tuberculosis; I should be inclined, however, to dismiss the tuberculin test on the basis of the clinical story and x-ray findings and make a diagnosis of generalized tuberculosis as the most likely explanation for this man's signs.

A PRINCIPAL: What is the effect of radiation on tuberculous adenitis?

DR HAMPTON: It was used for many years in the treatment with a dosage such as this patient had. I suppose the majority of people who treated such patients believed they improved. Much larger doses were given to active tuberculosis in the lung,

with the hope of fibrosing the process, and some workers have said that it improved active tuberculosis of the lung. I have done this accidentally, without any known effect. We had no hesitancy in treating this patient, even though our own first diagnosis was miliary tuberculosis, because if he had it, he had no hope of living, and if he had lymphoma we might put off death for a while. We gave a dose that we thought was safe even if he had miliary tuberculosis and could survive.

A PHYSICIAN: Does lymphoma never give a picture like this?

DR. HAMPTON: In the X-ray Department, we had quite a discussion about this case. In all the follow-ups on lymphoma, we have not seen a single example of a miliary process similar to this. We have had cases showing numerous nodules from 1 to 5 cm. in diameter but not a miliary process. We all admitted that some day we shall probably see one; there is no reason to suppose that we shall not.

A PHYSICIAN: Would this picture be consistent with septic infarcts?

DR. HAMPTON: I do not believe so.

#### CLINICAL DIAGNOSES

Diffuse lymphoma.

Miliary tuberculosis?

#### DR. BAKER'S DIAGNOSIS

Miliary tuberculosis, generalized.

#### ANATOMICAL DIAGNOSES

Miliary tuberculosis, generalized.

Tuberculous ulceration of duodenum, with perforation.

Tuberculosis of retroperitoneal lymph nodes.

Tuberculous enteritis, moderate.

Thrombosis of left adrenal vein.

Interadherence of aortic cusps, probably congenital.

Pulmonary edema, moderate, bilateral.

Tuberculous meningitis.

#### PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: Post-mortem examination showed very voluminous lungs, densely seeded, from top to bottom on both sides, with miliary

tubercles; some nodules were considerably larger than miliary tubercles, reaching 1 cm. in diameter. There was a slight tuberculous peritonitis. The duodenum was unusual. A large ulcer was found beyond the papilla in the third portion, where the duodenum crosses the vertebral column. We had never seen a peptic ulcer beyond the papilla of Vater, and later examination showed that the walls of this ulcer were caseous and it was purely tuberculous in origin. It communicated with a retroperitoneal abscess cavity, and whether the tuberculosis was primary in the duodenum, spreading through the intestinal wall, or a tuberculous retroperitoneal lymph node spread in the reverse direction into the duodenum, we cannot say. There were multiple tuberculous ulcers in the colon, several isolated tubercles in the meninges over the cerebellum and very early diffuse terminal tuberculous meningitis. There were peculiar lesions in the kidney and heart that did not look like tubercles but like septic abscesses, each about 1 cm. in diameter and filled with green purulent material, which grossly did not remotely suggest caseation, but later examination proved that these were also pure tuberculous abscesses. I have never seen a case of tuberculosis in which tubercle bacilli were so numerous. They even showed up in great numbers in the sections stained with eosin and methylene blue.

DR. HAMPTON: I think we can trace the origin of this process on the x-ray films. The gastrointestinal examination was done two months before death. At that time, the patient had this indefinite outline of the third portion of the duodenum, with an extrinsic mass and normal lung. One can assume that tuberculous adenitis was primary because the mucosa of the duodenum is not grossly abnormal and no definite ulcer is seen.

A PHYSICIAN: Was the mass in the groin tuberculous?

DR. MALLORY: A small caseous nodule 1 cm. in diameter was found there. There was no evidence of lymphoma.

DR. BAKER: Were there any sputum examinations for tubercle bacilli on the second admission?

DR. MALLORY: No.

A PHYSICIAN: Would you doubt now the diagnosis of lymphoblastoma on the previous biopsy?

DR. MALLORY: Completely.

Medicine* 8 Fenway Boston Massachusetts

## PROCUREMENT AND ASSIGNMENT SERVICE

The mailing of the enrollment forms and  
questionnaires for the Procurement and  
Assignment Service was completed on April  
24, and by now, every registered physician  
in the United States should have received  
them. These forms should be carefully  
filled out and **IMMEDIATELY** returned. If  
any physician has failed to receive the forms,  
he should write for them directly to the  
National Roster of Scientific and Specialized  
Personnel, 916 G Street, N. W., Washington,  
D. C.

## ANNUAL MEETING

THE one hundred and sixty-first anniversary  
of the Massachusetts Medical Society will be held  
at the Hotel Statler. The program of the meeting,  
which will be held on Monday, Tuesday and  
Wednesday, May 25, 26 and 27, appears elsewhere  
in this issue of the *Journal*.

The outstanding change in the usual sequence  
of events is one designed to permit all fellows of  
the Society to enjoy the scientific meetings more  
thoroughly than they have in the past; hence, the  
annual meetings of the supervising censors and  
Council will be held in the late afternoon and  
evening, respectively, of Monday, May 25, the day  
before the opening of the scientific sessions and  
the annual meeting of the Society.

The scientific papers to be presented at the  
four general sessions are largely concerned with  
War Medicine, that is, the application of  
medical science to war and its associated  
activities. Addresses by Dr. Frank H. Lahey,  
president of the American Medical Association,  
Dr. Morris Fishbein, editor of the *Journal of the  
American Medical Association*, Drs. Raymond A.  
Vonderlehr and Rolla E. Dyer, of the United  
States Public Health Service, and Mr. John M.  
Pratt, executive administrator of the National  
Physicians' Committee for Extension of Medical  
Services should be of particular interest. The  
Annual Oration will follow the annual meeting  
of the Society, to be held at eleven in the morning  
on Tuesday, May 26; the orator is Dr. William B.  
Castle, and his subject "Some Remarks on Therapy  
for Anemia." Following the annual dinner that  
evening, at which the guest speakers are Drs.  
Lahey and Fishbein, the Shattuck Lecture, "Medi-  
cine and Air Supremacy," will be given by Dr. John  
F. Fulton, of New Haven, Connecticut. The  
combined luncheons and meetings of the sections  
will be held on Wednesday noon, May 27, and  
extremely interesting topics have been chosen for  
discussion. As in previous years, there will be a  
continuous motion picture program during the  
two days of general sessions. The scientific and

technical exhibits will be extensive and comprehensive and promise, more than ever, to be of great educational value.

Transportation difficulties have necessitated a curtailment of the ladies' program. No out-of-town trip could be scheduled, but there will be a reception and tea at the Hotel Statler on Tuesday afternoon, May 26, followed by a dinner at The Copley-Plaza, and a luncheon at the Women's City Club, on Wednesday, May 27.

Since the Nation *is* at war, the program is not only timely but of extreme interest and value, and for being able to plan such a meeting, in spite of the difficulties engendered by war activities, the Committee of Arrangements deserves the sincere thanks of all members of the Massachusetts Medical Society, which can best be shown by a record-breaking attendance.

---

## THE ELLA SACHS PLOTZ FOUNDATION

ACCORDING to its eighteenth annual report, the Ella Sachs Plotz Foundation for the Advancement of Scientific Investigation awarded, during the past year, thirty-five grants for research in medicine and surgery and in related branches of science. Since its establishment, the foundation has supported four hundred and twenty-nine projects in the United States and thirty-seven other countries. The maximum sum given to any single experiment or study has usually been less than five hundred dollars.

Although the original intention of the foundation, as expressed by the trustees, was to assist research on single problems in stipulated fields, the policy in recent years has been to encourage investigations in the sciences closely related to medicine, without reference to special fields. Thus, the fund now supports experiments varying in scope and purpose from research on typhus and different serologic types of hemolytic streptococci to work in endocrinology and chemical embryology and studies on the physiologic effects of high altitudes.

Of particular interest to physicians in Massachusetts are the awards that were made to Dr. George Barkan, of Boston University School of Medicine; Dr. Austin M. Brues, of the Huntington Memorial Hospital; Dr. R. W. Hickman, of the Cruft Laboratory, Harvard University; Dr. Otto Krayner, of the Harvard Medical School; Dr. Fritz Lipman, of the Massachusetts General Hospital; and the Thorndike Memorial Laboratory, Boston City Hospital. The last-named gift was in recognition of Dr. Francis W. Peabody's services to the foundation.

The dramatic events of a world engaged in total war naturally occupy our minds and obscure, but do not obliterate, the accomplishments made possible by such organizations as the Ella Sachs Plotz Foundation. We can win this struggle to preserve our national integrity and way of life only by striking with all our force against an enemy in whose philosophy there is no room for liberty, justice, decency and honor. With the victories, we must accept temporary retreats; we must learn to bear the thought of the inevitable slaughter and destruction. But the peace must also be won—and kept. The silent and untiring workers engaged in research fight an unending war in which they can never admit defeat—a struggle against the growths, the viruses, the deficiency diseases that plague mankind. It is these men who will show us how to keep and enjoy the benefits of the peace we are striving and praying for.

---

## MEDICAL EPONYM

### OSGOOD-SCHLATTER'S DISEASE

Dr. Robert B. Osgood (b. 1873), of Boston, described "Lesions of the Tibial Tubercle Occurring During Adolescence" in the *Boston Medical and Surgical Journal* (148:114-117, 1903). The author made the following statements:

The adolescent tibial tubercle, from its situation and mode of development, is susceptible to injuries, especially in athletic subjects. These lesions are usually caused by a violent contraction of the quadriceps extensor.

Fracture and complete avulsions of the tubercle are rare, cause loss of function, and are easily diagnosed, usually clinically and always by means of the x-ray.

Avulsions of a small portion and partial separation of the tubercle are more common. They do not cause complete loss of function, but without treatment, long continued serious annoyance. The diagnosis should be made by a combination of the clinical and x-ray pictures, and before the latter are accepted as evidence both knees should be skiagraphed and accurate technique observed.

Professor Carl Schlatter (1864), of Zurich, independently discussed "Verletzungen des schnabel-förmigen Fortsatzes der oberen Tibiaepiphyse [Injuries to the Beak-shaped Process of the Upper Epiphysis of the Tibia]" in Bruns's *Beiträge zur klinischen Chirurgie* (38:874-887, 1903). A portion of the translation follows:

There occurs, in the region of the knee, a typical form of injury, not very uncommon, whose clinical picture, in spite of all the recent advances in diagnosis, is not yet satisfactorily clear to us, as I realize from a fruitless search for a comprehensive study of this injury in the literature, and also from my own errors in diagnosis. This is the separation of the beak-shaped process of the upper tibial epiphysis, which encompasses the head of the tibia anteriorly.

R. W. B.

## MASSACHUSETTS MEDICAL SOCIETY

### ANNUAL MEETING OF THE COUNCIL

The annual meeting of the Council will be held in the Georgian Room of the Hotel Statler, Boston, on Monday, May 25, 1942, at 7:00 p.m. This meeting will be preceded by the Cotting supper which will be served in Parlors A, B and C of the same hotel at 6:00 p.m.

#### Business:

1. Presentation of record of the special meeting of the Council held April 15, 1942, as published in the *New England Journal of Medicine*, issue of May 14, 1942.
2. Nominating Committee retires to deliberate.
3. Reports of standing and special committees.
4. Election of officers and orator.
5. Appointment of committees for ensuing year.
6. Such other business as may lawfully come before the meeting.

MICHAEL A. TIGHE, M.D., *Secretary*

### COMMITTEE ON MATERNAL WELFARE

#### CASE HISTORY: RUPTURE IN TUBAL PREGNANCY, FOLLOWED BY DEATH

A thirty-eight-year-old housewife was seen at 10:00 a.m. by her physician. She had fainted three

times and was reported to have abdominal colic with diarrhea. At 3:00 p.m. she was sent into the hospital in shock, practically pulseless, with no blood pressure, and died a few moments after admission. The past history was irrelevant. There had been one pregnancy twelve years previously, and the child was living and well. There was no history of skipped periods, although the hospital record was most inadequate. Autopsy revealed perforation of the right tube, and the abdomen was filled with blood clots.

*Comment.* The inadequacy of the history is characteristic of many small hospitals in Massachusetts. The new law placing the licenses under the Massachusetts Department of Public Health will undoubtedly rectify this neglect. In all probability, if a history had been obtained and recorded, it would have stated some irregularity in the menstrual cycle immediately preceding this fatality. That five hours elapsed between the time when the patient was seen at home and her arrival at the hospital allows no interpretation except ignorance on the part of the physician who saw this patient, or utter lack of appreciation of the seriousness of her condition. Without doubt, because this patient fainted three times before she was seen by a physician, evidence of hemorrhage must have been present, had the practitioner been intelligent enough to observe it. There is, of course, no excuse for this lapse of five hours.

No specific diagnosis was made prior to death. The autopsy was performed by a medical examiner. The death certificate assigned the cause of death to internal hemorrhage, and the autopsy proved the death to have been puerperal in origin.

Whether this patient had been seen by a physician before the morning of her death is not disclosed in the record. If irregular bleeding, which certainly must have occurred, stimulated the patient to consult a physician and if medical advice was obtained, this fatality can surely be attributed solely to poor medicine. It illustrates the fact that ruptures in tubal pregnancies can bleed to the point of exsanguination, and that the only way to prevent a fatal outcome is to make the patient with irregular flowing in the early months of pregnancy understand that medical advice must be sought, and to make the physician realize that irregular flowing in the early months of pregnancy may mean a tubal pregnancy, the only intelligent treatment of which is hospitalization, vaginal examination and laparotomy, whenever there is a question of a pathologic pelvis.

## PROGRAM OF THE ONE HUNDRED AND SIXTY-FIRST ANNIVERSARY OF THE MASSACHUSETTS MEDICAL SOCIETY

Monday, Tuesday and Wednesday, May 25, 26 and 27, Hotel Statler, Boston

The exercises of the one hundred and sixty-first annual meeting of the Society will be held at the Hotel Statler, Boston, on Monday, Tuesday and Wednesday, May 25, 26 and 27. It should be noted that the program for the first day, Monday, May 25, provides no scientific session; the golf tournament at the Commonwealth Country Club is scheduled for the afternoon, and the annual meetings of the supervising censors and Council for the late afternoon and evening, respectively.

The Committee of Arrangements, which has planned the meeting, consists of Drs. William T. O'Halloran, chairman, James A. Halsted, George P. Sturgis, Henry H. Faxon and Gordon M. Morrison.

With the exception of some of the section meetings and luncheons, all activities will be located at the Hotel Statler. The scientific exhibits will fill the Ballroom Assembly, and the technical exhibits will occupy the Ballroom. On Tuesday and Wednesday, both in the morning and in the afternoon, motion pictures will be shown in the Lower Foyer.

The members' registration desk will be in the Ballroom, and that of the ladies on the Mezzanine Floor. All who attend are earnestly requested to register.

According to the arrangement a year ago, the annual dinner will be followed by the Shattuck Lecture, the dinner being scheduled to start at 7:00 p.m., Tuesday.

The luncheon meetings of the sections will be held Wednesday noon. Since it is necessary to have some idea of the number of members at these luncheons, all are urged to notify the committee at once if they plan to attend.

### MONDAY EVENING, MAY 25

#### Annual Meeting of the Council of the Massachusetts Medical Society

- 5:00 **Supervising Censors' Meeting** (Hancock Room).
- 6:00 **Cotting Buffet Supper** (Parlors A, B and C).
- 7:00 **Council — Annual Meeting** (Georgian Room).
- Nominating Committee** (Hancock Room).

### TUESDAY MORNING, MAY 26

#### First General Session

Georgian Room

Dr. Cadis Phipps, *Chairman*

Dr. Edward J. O'Brien, Jr., *Co-Chairman*

- 9:20 **Scarlet Fever Today.** Dr. Edwin H. Place: physician-in-chief, South Department, Boston City Hospital; clinical professor of pediatrics, Tufts College Medical School.

- 9:40 ***The Problem of Certain Tropical Diseases in War.*** Dr. Henry E. Meleney (New York City): Hermann M. Biggs Professor of Preventive Medicine, New York University College of Medicine.

- 10:00 ***Trauma of the Skin Due to Wartime Activities.*** Dr. John G. Downing: assistant professor of dermatology, Tufts College Medical School; dermatologist, Boston City Hospital and St. Elizabeth's Hospital.

- 10:20 ***Massachusetts Public-Health Problems in Wartime.*** Dr. Paul J. Jakmauh: Commissioner, Massachusetts Department of Public Health.

- 10:40 ***The Impact of the War on the Venereal Disease Problem.*** Dr. Raymond A. Vonderlehr (Washington, D. C.): Assistant Surgeon General, Division of Venereal Diseases, United States Public Health Service.

#### 11:00 **Annual Meeting of the Massachusetts Medical Society.**

Georgian Room

**Annual Oration** (following business meeting): *Some Remarks on Therapy for Anemia.* Dr. William B. Castle: professor of medicine, Harvard Medical School; associate director, Thorndike Memorial Laboratory; director, Second and Fourth Medical Services, Boston City Hospital.

**Annual Luncheon** (Parlors A, B and C): tickets may be procured at the Registration Desk.

### TUESDAY AFTERNOON, MAY 26

#### Second General Session

Georgian Room

Dr. George Leonard Schadt, *Chairman*  
Dr. Ralph R. Stratton, *Co-Chairman*

- 2:00 ***Hospital Preparedness.*** Dr. Charles F. Wilkins: executive director, Beth Israel Hospital; chief of Emergency Medical Services for Suffolk County.

- 2:20 ***Medical-School Plans for the Emergency.*** Dr. Bennett F. Avery: dean, Boston University School of Medicine; Waterhouse Professor of Anatomy, Boston University School of Medicine.

- 2:40 ***The Doctor's Role in First Aid.*** Dr. A. William Reggio: visiting surgeon, Massachusetts General Hospital; deputy director, Medical Division, Massachusetts Committee on Public Safety.

- 3-00 *Civilian Medical Defense in Massachusetts* Dr Elliott C Cutler Moseley Professor of Surgery, Harvard Medical School, surgeon-in-chief, Peter Bent Brigham Hospital, director, Medical Division, Massachusetts Committee on Public Safety
- 3-10 *American Medicine and the War* Dr Morris Fishbein (Chicago) editor, *Journal of the American Medical Association*
- 3-20 *Tuberculosis Increasing?* Dr John A Foley professor of medicine, Boston University School of Medicine, chief-of-staff, Boston Sanatorium director, Fifth and Sixth Medical Services, Boston City Hospital
- 4-00 *The Interrelationship of Anesthesia with Analgesia* Dr Joseph F McCarthy (New York City) director, Department of Urology, New York Polyclinic Medical School and Hospital
- 4-20 *Hypertension Present status of the problem* Dr Robert W Wilkins assistant professor of medicine, Boston University School of Medicine
- 4-40 *The Present Program for the Immunization of Troops* Dr John F Enders assistant professor of bacteriology, Harvard Medical School

## TUESDAY EVENING, MAY 26

### Annual Dinner of the Massachusetts Medical Society

SALLE MODERNE

7 00 pm

#### Guest Speakers:

Dr Frank H Lahey president, American Medical Association

Dr Morris Fishbein (Chicago) editor, *Journal of the American Medical Association*

*The Shattuck Lecture (GEORGIAN ROOM) (following annual dinner) Medicine and Air Supremacy* Dr John F Fulton (New Haven, Connecticut) Sterling Professor of Physiology, Yale University School of Medicine

## WEDNESDAY MORNING, MAY 27

### Third General Session

GEORGIAN ROOM

Dr A A Hornor, *Chairman*

Dr Edward P Bagg, *Co Chairman*

- 9-00 *Carcinoma of the Bronchus* Dr George W Holmes professor of clinical roentgenology emeritus, Harvard Medical School consulting roentgenologist, Massachusetts General Hospital
- 9-20 *Clinical Application of Gastrosocopy* Dr Charles W McClure junior visiting physician and gas-troscopist, Fifth Medical Service, Boston City Hospital, and Dr I R Jankelson assistant professor of medicine, Tufts College Medical School junior visiting physician, Boston City Hospital

- 9-40 *The Procurement and Assignment of Physicians during the Present Emergency* Dr Reginald Fitz Massachusetts State Chairman, Procurement and Assignment Service, Office of Defense, Health and Welfare Services
- 10-00 *The Relation of Medicine to the Emergency* Dr Frank H Lahey president, American Medical Association, chairman, Procurement and Assignment Service director of surgery, Lahey Clinic, surgeon-in-chief, New England Deaconess Hospital and New England Baptist Hospital
- 10-20 *Management of the Acute Stage of Infantile Paralysis* Dr Frank R Ober John B and Buckminster Brown Clinical Professor of Orthopaedic Surgery, Harvard Medical School, chief of Orthopedic Department, Children's Hospital, orthopedic surgeon, Peter Bent Brigham Hospital, chief surgeon, New England Peabody Home for Crippled Children
- 10-40 *Typhus Fever* Dr R E Dyer (Bethesda, Maryland) director National Institute of Health, United States Public Health Service
- 11-00 *Industrial Health in National Defense* Dr Daniel L Lynch medical director, New England Telephone and Telegraph Company
- 11-20 *A Further Report on Para Aminobenzoic Acid and Its Relation to Gray Hair* Dr Benjamin F Sieve instructor in medicine, Tufts College Medical School junior visiting physician, Boston City Hospital
- 11-40 *World Conflict and Medical Service* Mr John M Pruitt (Chicago) executive administrator, National Physicians' Committee for the Extension of Medical Services

## WEDNESDAY NOON, MAY 27

### Section Meetings and Luncheons

12 00 m-2 00 pm

### Sections of Medicine and Surgery

PARLORS A, B AND C

- Dr Erwin C Miller, Worcester, *Chairman—Medicine*  
 Dr Charles L Short, Boston, *Secretary—Medicine*  
 Dr Grantley W Taylor, Boston, *Chairman—Surgery*  
 Dr James C McCann, Worcester, *Secretary—Surgery*
- The Vascular Dynamics Recognition and Management of Shock* Dr Virgil H Moon (Philadelphia) professor of clinical pathology, Jefferson Medical College of Philadelphia

### Section of Pediatrics

THE JUNIOR LEAGUE, ZERO MARLBOROUGH STREET

Dr Philip H Sylvester, Boston *Chairman*  
 Dr James Marvin Baty, Brookline, *Secretary*

*The Common Cold* Dr Francis L Weille associate surgeon, Massachusetts Eye and Ear Infirmary, assistant in otolaryngology, Harvard Medical School

**Section of Obstetrics and Gynecology**

THE TAVERN CLUB, 4 BOYLSTON PLACE

Dr. M. Fletcher Eades, Boston, *Chairman*Dr. Raymond S. Titus, Boston, *Secretary*

*Vaginal Discharge.* Dr. John Rock: visiting surgeon, Free Hospital for Women; instructor in gynecology and research associate in obstetrics, Harvard Medical School.

**Section of Radiology and Physiotherapy**

PARLORS D AND E

Dr. Joseph H. Marks, Boston, *Chairman*Dr. Henry A. Tadgell, Wrentham, *Secretary***Symposium on Bronchial Obstructions.**

Dr. Edward B. Benedict: assistant in surgery, Harvard Medical School; associate visiting surgeon, Massachusetts General Hospital.

Dr. Richard H. Overholt: thoracic surgical consultant, New England Deaconess Hospital and Corey Hill Hospital; surgeon-in-chief, Thoracic Clinic, Boston Dispensary.

Dr. Merrill C. Sosman: clinical professor of roentgenology, Harvard Medical School; roentgenologist-in-chief, Peter Bent Brigham Hospital.

**Section of Dermatology and Syphilology**

PARLOR F AND THE HANCOCK ROOM

Dr. Arthur M. Greenwood, Boston, *Chairman*Dr. William J. Macdonald, Boston, *Secretary*

*Eczema and Pruritus in the Aged.* Dr. Leonard E. Anderson: dermatologist, Out-Patient Department, Springfield Hospital; dermatologist, Wesson Memorial Hospital, Springfield.

WEDNESDAY AFTERNOON, MAY 27

**Fourth General Session**

GEORGIAN ROOM

Dr. Donald Munro, *Chairman*Dr. Frederick J. Lynch, *Co-Chairman*

2:00 *The Early Treatment of Burns.* Dr. Donald W. MacCollum: associate in surgery, Harvard Medical School; associate in plastic surgery, Peter Bent Brigham Hospital; associate visiting surgeon, Children's Hospital.

2:20 *The Five-Year Report on Cesarean Section in Massachusetts (1937-1941).* Dr. Robert L. DeNormandie: member, State and Federal Advisory Committees on Maternal and Child Hygiene.

2:40 *The Choice of Drug in the Treatment of Infections.* Dr. Charles H. Rammelkamp: instructor in medicine, Boston University School of Medicine.

3:00 *Deficiency Diseases of the Oral Cavity.* Dr. David Weisberger: instructor in oral medicine, Harvard Dental School.

3:20 *The Sequela of War Head Injuries.* Dr. Derek Denny-Brown: professor of neurology, Harvard Medical School.

3:40 *War Dermatology.* Dr. C. Guy Lane: clinical professor of dermatology, Harvard Medical School; chief of Department of Dermatology, Massachusetts General Hospital.

4:00 *Symposium on Minor Psychiatric Disturbances in War and Civilian Life.*

*The Diagnosis of Psychoneurotic Disturbances.* Dr. Donald J. MacPherson: associate in medicine, Peter Bent Brigham Hospital.

*The Psychiatric Approach in Medicine: Psychosomatic medicine.* Dr. Jacob E. Finesinger: assistant professor of psychiatry, Harvard Medical School; psychiatrist, Massachusetts General Hospital.

*Therapy in the Psychoneuroses.* Dr. Erich Lindemann: associate in psychiatry, Harvard Medical School; associate psychiatrist, Massachusetts General Hospital.

**Motion Picture Program**

LOWER FOYER

Tuesday, May 26

- 9:30-10:30 *Prevention and Treatment of Eclampsia.*  
 10:30-10:45 *Diagnostic Procedures in Tuberculosis.*  
 10:45-11:00 *Emergency Treatment for Fractures.*  
 11:00-11:30 *Technique of Blood Transfusions.*  
 11:30-12:00 *Treatment of Asphyxia Neonatorum.*  
 2:00- 2:45 *Diagnosis and Treatment of Infections of the Hand.*  
 2:45- 3:15 *First Aid in Transporting Fractures of the Leg, Spine and Arm.*  
 3:15- 3:30 *Protruded Intervertebral Disk: Diagnosis and surgical treatment.*  
 3:30- 4:00 *Cardiac Irregularities.*  
 4:00- 4:15 *Splenectomy.*  
 4:15- 4:30 *The Use of Extra Fine Catgut.*

Wednesday, May 27

- 9:30-10:30 *Sex Hormones, Physiology, Diagnosis and Therapy.*  
 10:30-11:00 *Vaginal Hysterectomy: Suture method.*  
 11:00-11:15 *Vaginal Hysterectomy: Clamp method.*  
 11:15-11:45 *Treatment of Burns.*  
 2:00- 2:15 *Transverse Cervical Cesarean Section.*  
 2:15- 2:30 *Hernioplasty.*  
 2:30- 3:15 *Physiology and Conduct of Normal Labor.*  
 3:15- 3:45 *Acute Appendicitis.*  
 3:45- 4:30 *Arteriosclerotic Heart Disease.*

**Scientific Exhibits**

BALLROOM ASSEMBLY

Booth

- S-10 *The Pathology of Skin Tumors.* Massachusetts State Tumor Diagnostic Service. Exhibitors: Dr. Shields Warren and Dr. Olive Gates.

15-16 *First Aid in Fractures* Massachusetts Committee on Fractures and Trauma, American College of Surgeons, Medical Division, Massachusetts Committee on Public Safety, Boston Metropolitan Chapter, American Red Cross

17 *Study and Treatment of Alcoholism* The Washingtonian Hospital Exhibitor Dr Merrill Moore, director of research

18 *The Senescent Skin and Its Diseases* Dr C Guy Lane, Dr Arthur M Greenwood and Dr Ethel M Rockwood

19 *Blood for Victory* Blood Donor Center, Boston Metropolitan Chapter, American Red Cross Exhibitor Mr Wesley Fuller, director

20 *Sigmoidoscopy* The Gastrointestinal Clinic, Boston City Hospital Exhibitors Dr Charles W McClure and Dr I R Jankelson

21 *Intercapillary Glomerulosclerosis* Fifth and Sixth Medical Services, Boston City Hospital Boston University School of Medicine Mallory Institute of Pathology, Boston City Hospital Exhibitors Dr Harold Jeghers and Dr Oscar Wollenman

22-24 *Biliary Tract Disease* Evans Memorial Hospital Massachusetts Memorial Hospitals, Boston

1 *Gallstones Composition and etiology* Dr Knowles B Lawrence

2 *Röntgenologic Study of the Gallbladder* Dr George Levene

3 *Pathology of Acute Cholecystitis* Dr Charles F Branch

4 *Surgical Treatment of Acute Cholecystitis* Dr Howard M Clute

5 *Duodenal Drainage* Dr Franz J Ingelinger

6 *Structures of the Common Duct* Dr Howard M Clute

7 *Gallstone Ileus* Dr Egon G Wissing and Dr Knowles B Lawrence

8 *Preoperative and Postoperative Care in Obstructive Jaundice* Dr Thomas J Anglem

25-26 *Anesthesia* Massachusetts members of the New England Society of Anesthesiology

27 *Fractures* The Faulkner Hospital Exhibitors Dr Gordon MacK Morrison and Dr Harvey R. Morrison

28-29 *New Standards of Efficiency of Treatment in Diabetes Mellitus* Dr Elliott P Joslin and associates

30-31 *Skeletal Traction and Countertraction Methods Applicable to Ordinary Extension Splints Used in the Treatment of the Fractures of the Lower Extremity Rupture of Biceps Brachii* United States Marine Hospital, Boston Exhibitor Dr Richey L Waugh

32-33 *Surgical Pathology* The Fallon Clinic Worcester Exhibitors Dr John Fallon, Dr James T Brosnan and Dr William G Moran

34 *Occupational Therapy* Massachusetts Association for Occupational Therapy

CORRIDOR

A *Diseases of the Biliary Tract* The Lahey Clinic Exhibitors Department of Surgery

B *Nutrition* Massachusetts Department of Public Health

### ANNUAL GOLF TOURNAMENT

The annual golf tournament of the Massachusetts Medical Society will be held at the Commonwealth Country Club, 91 Algonquin Road, Chestnut Hill (Newton), on Monday, May 25. The Burrage Bowl, the Society's championship trophy for the lowest net score, and other prizes for both net and gross play should stimulate interest in this tournament. Play will begin at 1:00 p.m. The greens fee for 18 holes is \$2.00; for two or more rounds, \$2.50. For additional information, communicate with Mr. Robert St. B. Boyd, executive secretary, 8 Fenway, Boston (KEN 2094), or a member of the Golf Committee, which is composed of the following: Dr. Roy J. Heffernan, Chairman, Dr. Edward A. Cooney, Dr. Thomas E. Dinan, Dr. Allan L. Davis and Dr. Roger T. Doyle.

### COMMITTEE ON POSTGRADUATE INSTRUCTION

A luncheon meeting of the district chairmen of the Committee on Postgraduate Instruction will be held on the fourth floor of the Hotel Statler on Wednesday, May 27, at 12:30 p.m. (Inquire at information desk for the room number.)

### MASSACHUSETTS MEDICO-LEGAL SOCIETY

A meeting of the Massachusetts Medico-Legal Society will be held on the fourth floor of the Hotel Statler on Tuesday, May 26, at 2 p.m. (Inquire at information desk for the room number.)

### DEATHS

**BALDAUF**—LEON K. BALDAUF, M.D., of Waltham died April 30. He was in his sixty-fifth year.

Dr. Baldauf received his degree from Johns Hopkins University School of Medicine in 1905. He became a member of the faculty of Albany Medical College and later served as professor of pathology and bacteriology University of Louisville School of Medicine. He had recently been appointed professor of pathology at Middlebury University School of Medicine. He was a member of the Massachusetts Medical Society and the American Medical Association.

His widow survives him.

**BARNES**—FRANCIS J. BARNES, M.D., of Cambridge died April 28. He was in his eightieth year.

Born in Newton, Dr. Barnes received his degree from Harvard Medical School in 1888. From 1916 to 1926 was chief of staff of the Cambridge City Hospital. He was a member of the Massachusetts Society of Examining Physicians, and was a fellow of the Boston Medical Library, the Massachusetts Medical Society and the American Medical Association.

He is survived by his widow, a daughter and two grandchildren.

**BENSON**—CHARLES S. BENSON, M.D., of Haverhill died April 30. He was in his seventieth year.

Born in Lewiston, Maine, Dr. Benson received his degree from Columbia University College of Physicians and Surgeons in 1896. He had practiced surgery in Essex County for many years and was the head of the Benson Hospital. Dr. Benson was vice-chairman of the medical advisory board of District No. 4, Selective Service System, and had served as a draft-board physician during World War I. He was a former president of the Essex North District Medical Society, and was a fellow of the American College of Surgeons, the Massachusetts Medical Society and the American Medical Association.

**CELCE**—FRANK F. CELCE, M.D., of Holyoke, died April 28. He was in his seventy-fifth year.

A native of Germany, Dr. Celce received his degree from University of Pennsylvania School of Medicine in 1893. He was a member of the Massachusetts Medical Society and the American Medical Association.

A son and a daughter survive him.

**DAMON**—ARTHUR L. DAMON, M.D., of North Woburn, died April 30. He was in his seventy-fifth year.

Born in West Cummington, Dr. Damon received his degree from University of Vermont College of Medicine in 1890. He was a fellow of the Massachusetts Medical Society and the American Medical Association.

His widow, a brother and a sister survive him.

**DURGIN**—EDWARD C. DURGIN, M.D., of Marshfield died April 26. He was in his sixty-fifth year.

Dr. Durgin received his degree from Tufts College Medical School in 1901. He was a former member of the Massachusetts Medical Society and the American Medical Association.

## THE DIFFERENTIAL DIAGNOSIS OF ACUTE APPENDICITIS AND ACUTE GASTROENTERITIS IN COLLEGE MEN\*

THOMAS B. QUIGLEY, M.D.† AND ANDREW W. CONTRATTO, M.D.‡

CAMBRIDGE, MASSACHUSETTS

ANY addition to the enormous and exhaustive literature of appendicitis requires some sort of apology. The present study was undertaken to clarify somewhat, if possible, the usually simple, but occasionally very difficult, differential diagnosis between acute appendicitis and acute gastroenteritis. Every practitioner of experience has at times been faced with the problem presented by the following case:

CASE 1 C. P., a 20-year-old undergraduate, first presented himself for treatment about 48 hours after the onset of an illness characterized by nausea, vomiting, mild mid-abdominal pain and diarrhea. The temperature was 96°F., and the abdomen was quite normal. The white-cell count was 30,800. The patient was advised to remain in his quarters, to eat a light diet and to return the next day. Twenty-four hours later, he stated that he felt better. The nausea and vomiting had ceased, but the abdominal pain persisted. The temperature was 99.4°F., and the white-cell count was 32,100. An experienced surgeon saw the patient at that time and noted nothing abnormal on examination of the abdomen other than rather loud, vigorous peristalsis. Furthermore, there was nothing remarkable on rectal examination.

The next day, the 4th day of the illness, the symptoms were unchanged, but there was for the first time diffuse abdominal and rectal tenderness. Operation was advised and agreed to. A ruptured pelvic appendix was found and removed. Convalescence was rather stormy, and 7 weeks later another laparotomy was carried out for intestinal obstruction. The patient missed, in all, 42 days of classes.

With the possibility of such near tragedy in the background, the surgeon may choose to operate in a doubtful case and, after removing a normal or "slightly injected" appendix, console himself with the thought that the most serious possibility has been ruled out and the patient is certain to recover. Although there will probably always be a small number of cases in which a correct diagnosis

cannot be established without laparotomy, it is a rather heroic diagnostic procedure, and in college men at least, it may have far-reaching effects, as illustrated by the following case:

CASE 2 S. J., an 18-year-old college freshman, was awakened from sleep by crampy, fairly constant, lower abdominal pain and nausea. The pain continued through the morning and became localized in the right lower abdominal quadrant. There were several loose watery bowel movements. At the time of examination, in the mid-afternoon, the temperature was 101.4°F., and the white-cell count 15,000. Spasm, tenderness and slight rebound tenderness were present in the right lower abdomen. There was moderate, diffuse rectal tenderness. Three experienced surgeons independently examined the patient, and each advised immediate operation for acute appendicitis.

At operation, 10 hours after the onset of the illness, a "scarred" but otherwise normal appendix was removed. No other abnormality was found on exploration. Convalescence was uneventful, and the patient resumed his classes 24 days later.

This boy's illness occurred at the beginning of his first period of college examinations. He was an industrious though not brilliant student and was enabled to attend college only by the grant of a scholarship. To keep the scholarship, he had to achieve honor grades in the examinations. Arrangements were made for him to take these in the hospital, the first on his fifth postoperative day. Fortunately, he did well, and was able to continue his college career. Needless to say, had he failed, his whole career might have been changed.

\* \* \*

The records of 100 cases of acute gastroenteritis and 60 cases of appendicitis occurring in Harvard University undergraduates between 1938 and 1941 were studied. In almost every case, the patient was seen by some member of the staff of the Department of Hygiene within twelve hours of the onset of the illness. All those with gastroenteritis were treated at the Stillman Infirmary. Only those cases of appendicitis were included in which operation

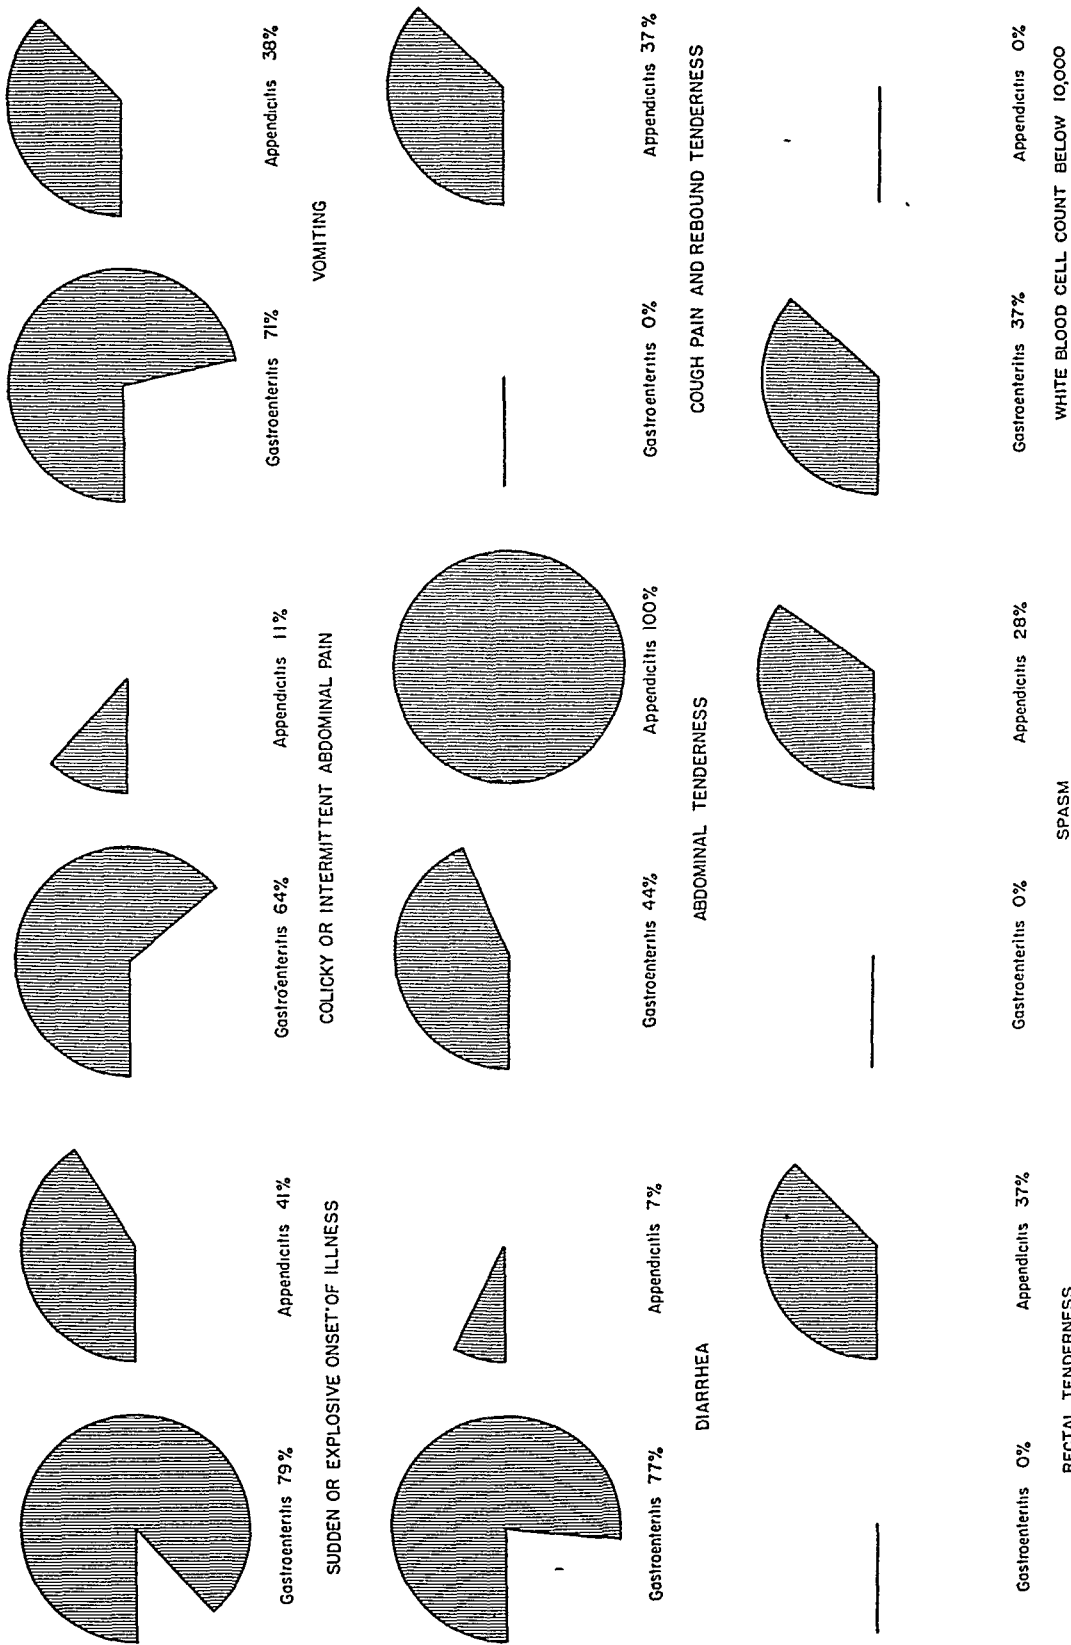

FIGURE 1.

had been carried out at a Boston hospital affiliated with the Harvard Medical School, and in which the pathologist's diagnosis agreed with the surgeon's and was unquestionably acute appendicitis. No deaths occurred in either series. The average time absent from classes for the patient with gastroenteritis was two days—for those with appendicitis, twenty days.

The records were studied with certain points in the history, physical examination and data from the laboratory in mind: the onset of the illness, whether explosive or insidious; the character and location of the abdominal pain; the presence or absence of nausea, vomiting, diarrhea and chills; the degree of fever and leukocytosis; and the presence or absence of abdominal spasm and tenderness.

The results are best described with reference to each of the signs and symptoms studied.

#### *Onset of Illness*

A sudden or explosive onset was more characteristic of gastroenteritis, occurring in 79 per cent, whereas in 59 per cent of the cases of appendicitis the onset was gradual or insidious (Fig. 1).

#### *Severity of Pain*

An attempt was made to classify the degree of abdominal pain as mild, moderate or severe, although such pain is admittedly difficult to evaluate and involves personal variations in sensitivity. Aside from the fact that 19 per cent of the patients with gastroenteritis had no pain whatever, no significant differences were found in the two groups. In 49 per cent of the appendicitis and 79 per cent of the gastroenteritis cases, the pain could be classified as mild. Severe pain was found in only 3 per cent of the appendicitis series.

#### *Character of Pain*

Steady abdominal pain occurred in 89 per cent of the appendicitis cases, whereas 64 per cent of the patients with gastroenteritis who had pain described it as colicky or intermittent.

#### *Localization of Pain*

Of the patients with appendicitis, 24 per cent described their pain as diffuse or general; 8 per cent placed it in the upper abdomen and 68 per cent in the lower abdomen. More than twice as many patients with gastroenteritis, or 58 per cent, were unable to localize the pain; 28 per cent described it as occurring in the upper abdomen, and only 12 per cent in the lower abdomen.

#### *Vomiting*

Vomiting occurred almost twice as often in the cases of gastroenteritis—in 71 per cent, as compared with 38 per cent in the appendicitis series.

#### *Diarrhea*

As might be expected, 77 per cent of the patients with gastroenteritis complained of diarrhea. Loose, repeated bowel movements occurred in only 4 cases of appendicitis, and 2 of these patients had taken cathartics. Ten other patients with appendicitis who had taken cathartics failed to develop diarrhea. In a review of the records, the value of closely questioning the patient on this point became apparent. Often, he states that he has had diarrhea, when actually there have been only one or two somewhat loose bowel movements.

#### *Chills*

Although often mentioned as an important diagnostic point, true chills did not occur in either series.

#### *Hyperperistalsis*

The presence of loud, rapid borborygmi was described in 44 per cent of the cases of gastroenteritis and 10 per cent of the cases of appendicitis, roughly paralleling the occurrence of diarrhea.

#### *Tenderness*

Mild tenderness was present in 44 per cent of the cases of the gastroenteritis group: 26 in the lower abdomen, and 18 above the umbilicus. Every patient with appendicitis exhibited some degree of abdominal tenderness when examined. In only 1 case was it above the umbilicus; in 2, it was described as equal in both lower quadrants, and in the remaining 95 per cent it was confined to the right lower quadrant. Cough pain and rebound tenderness were present in 37 per cent and were of great diagnostic significance, occurring in none of the cases of gastroenteritis. Rectal tenderness was also confined to the patients with appendicitis, occurring in 37 per cent. It was noted repeatedly that strain of the abdominal muscles associated with vomiting and retching can produce a superficial sort of tenderness and even slight voluntary spasm. As a rule, however, this is confined to the upper abdomen and is not elicited with the patient fully relaxed.

#### *Spasm*

The evaluation of abdominal spasm is at best difficult in its early stages, but it is of significance that it was described in 28 per cent of the patients with appendicitis and in none of those with gastroenteritis.

#### *Fever*

The average temperature for the cases of gastroenteritis was 99.1°F., and for the appendicitis group 98.8°F. It is perhaps significant that although 9 per cent of the former exhibited temperatures of

more than 101°F. by mouth, only 1 in the latter group was recorded.

#### *White-Cell Count*

The average white-cell count was a little higher for appendicitis: 18,300 as compared with 12,400 for gastroenteritis. Of greater consequence was the finding that none of the appendicitis cases had a white-cell count of less than 10,000, whereas 37 per cent of the gastroenteritis series did.

\* \* \*

Although, as a rule, the diagnosis is clear and straightforward between gastroenteritis and appendicitis, in the exceptional and bizarre cases the following diagnostic points appear to be worthy of consideration.

An explosive onset, colicky abdominal pain, vomiting, diarrhea, high fever and a white-cell count

below 10,000 and bizarre or absent abdominal signs appear to be characteristic of gastroenteritis.

An insidious onset and a steady abdominal pain, on the other hand, favor the diagnosis of appendicitis. Tenderness and true spasm are of the greatest importance, and rebound or cough tenderness referred to the right lower abdominal quadrant is almost pathognomonic.

#### SUMMARY

Attention is called to the urgency of a correct differential diagnosis between acute gastroenteritis and acute appendicitis in college men.

The symptoms, signs and laboratory data in 100 cases of acute gastroenteritis and 60 cases of proved appendicitis are reviewed, and the significant differences summarized.

## COLLES'S FRACTURE: A STUDY OF X-RAY FILMS BEFORE AND AFTER REDUCTION\*

JAMES W. SEVER, M.D.†

BOSTON

THIS study is an effort to determine, by means of roentgenograms, what should constitute a satisfactory anatomic reduction following a Colles's fracture. Measurements of the degree of deformity of the distal fragment of the radius in relation to the long axis of the shaft before and after reduction were made. X-ray interpretations by the roentgenologist were checked and occasionally discarded as unreliable and optimistic, in relation to the actual anatomic findings. It is obvious from this study that surgeons and roentgenologists need further care and instruction in methods of satisfactory reduction of such fractures and in the more careful interpretation that should be offered in any given case by study of the plate. Strict consideration of the normal anatomic relations should always be the criterion by which a good or unsatisfactory reduction is reported to the surgeon. This study does not undertake to report on the functional results, which are to be reported in a later paper in which the anatomic findings will be correlated with the functional results so far as possible.

In this report, 199 cases of Colles's fractures were studied, and so far as the x-ray films were available before and after reduction, measurements

were made from them. In each plate, a line was drawn parallel to the long axis of the radius in the lateral plane, and another line was drawn parallel to the plane of the radiocarpal joint. Then, with a transparent protractor, the joint angle was determined in relation to the long axis of the radius. In this way, an excellent and fairly accurate determination of the amount of the original deformity or displacement of the distal radial fragment and of the relative degree of replacement following reduction was obtained.

A few degrees one way or the other must be allowed for error in such measurements. In many cases, the angle of rotation of the forearm varied, but the roentgenologist assured me that this rotation would not alter to any great extent the joint angle as I determined it, so long as it was a reasonable attempt at a lateral view.

There were 40 men and 159 women in this series. The right wrist was fractured in 89 cases and the left in 112 cases; the ulnar styloid was fractured in 84 cases. There was a great variety in the types of fractures noted—from the simple fracture of the lower end of the radius, often without much displacement, to the severe comminuted fractures, with considerable displacement of the fragments in all directions. No attempt is made in this report to classify them further, since such a classification would be useful only for two rea-

\*Read at the annual meeting of the New England Surgical Society, Hanover, New Hampshire, September 5, 1941.

sions—namely, an anatomic one, and one having to do with function in relation to the types of fracture. These factors will be considered in the later report on function. No cases of reverse

FIGURE 1.

*These films show excellent reduction, however, the postreduction view is not a true lateral*

Colles's fracture or the so-called "Smith fracture" were seen in this series.

An average of 181 cases showed the degree of deformity, or backward rotation of the radiocarpal joint before reduction, to be  $-28^\circ$  from the perpendicular. Ten cases had an average of  $7.8^\circ$ , which is about half normal. The normal forward palmar inclination of the radiocarpal joint to the long axis of the radius averages about  $15^\circ$  beyond the right angle; that is, the joint, with the hand pronated, faces distinctly downward to allow for full and free flexion. All measurements noted in this report are, however, to be considered plus or minus, in relation to a right angle, to the long axis of the shaft of the radius. In the anteroposterior view, the concave articular surface of the radius faces inward at an angle of about  $25^\circ$ . Following reduction, a number of patients had no check-up films, so that data regarding a satisfactory reduction could not be obtained.

In patients on whom check-up x-ray studies were made, it was found that 36 cases were reduced to only  $90^\circ$ , and 24 cases had an average residual deformity, after reduction, of  $-8.3^\circ$ . In other words, these 60 cases, or approximately 39 per cent, were not at all satisfactorily reduced. In 92 other postreduction cases, the average angle was determined as  $+10.9^\circ$ , which, for an average, was fairly satisfactory, but individual cases varied from  $+5^\circ$  to  $+30^\circ$ .

Besides these evident poor reductions of the gross backward deformity, often with persistence of the typical silver-fork appearance, there was a marked lapse in correction of the radial deviation of the hand. In this way, and because of the lack of correction of these two primary and major fac-

FIGURE 2

*This case had considerable prereduction deformity, which was not wholly corrected.*

tors, it was evident that the main problem of reduction of the fracture had not been grasped.

Fractures that had been reduced by surgeons of experience and skill generally showed an excellent anatomic result. In the other cases, there were many lapses, owing, I believe, to lack of knowledge

of what had actually happened, and how to correct it adequately.

For many years, Colles's fractures have been regarded as simple fractures, which anyone could treat, and this point of view has been emphasized by the rather loose teaching of a number of men who should have known better. All that was necessary, it was stated, was a simple, single motion of flexion of the wrist following breaking up of the impaction of the radius. Adduction of the hand was not insisted on as a means not only of restoring length to the radius but also of re-establishing the relation of the radioulnar joint. As a result, flexion of the wrist in plaster, following an attempted reduction, has been all that has been

ing of the distal radial fragment has not been wholly reduced. Wrist flexion has become the position in which it has been assumed that the fracture has been satisfactorily reduced, when that is often not true. The hand is generally only pulled on and the wrist flexed, without any real attempt to manipulate and reduce the radial fragment. Ade-

FIGURE 3.

*In this case, there was excellent reduction, even though the postreduction film is not a true lateral.*

done in many cases. In this study of x-ray films, I have seen many in which the wrist is only moderately flexed—the motion occurring at the radio-carpal joint, but limited, because the backward tilt-

FIGURE 4.

*These films show a bad deformity that was corrected to a right angle only; the reduction was excellent.*

quate reduction of the backward angulation of the radial fragment is not accomplished—or rarely so—by flexion of the wrist alone. Flexion and adduction of the wrist should be only secondary positions, following adequate reduction of the fracture itself, and merely to prevent recurrence of the deformity.

In my opinion, there is no one and universal method by which a Colles's fracture may be easily and successfully reduced, but certain procedures, such as loosening of the impaction, flexion of the backwardly rotated distal fragment and adduction of the hand, are essential. In part, I believe, this complacent attitude has been the result of the lack of knowledge on the part of the physicians in interpreting the x-ray films, and of the optimism of the roentgenologist in reporting "good position" or "satisfactory reduction following manipulation" when such a report should never have been made. In many of these cases, there has been only slight reduction, if any, of the rotation of the distal radial fragment, and very little consequent restoration of the normal joint angle. This, I believe, is the fault of both the surgeon and the roentgenolo-

gist and is due to ignorance and faulty observations on the part of both. A proper measurement of the

FIGURE 5.

*In this case, there was a badly comminuted fracture, in which all the carpal bones were in front of the long axis of the radius; an excellent reduction was obtained*

displacement before and after reduction should be part of the x-ray record and should be so reported.

321 Dartmouth Street

#### DISCUSSION

Dr OTTO J. HERMANN (Boston): The first thing I should like to mention is the use of the term "Colles's fracture." I have instructed my interns not to use that designation or "Pott's fracture" as a final diagnosis. When such general terms are used, they should be followed by an anatomic description of the fracture.

Several years ago, in an excellent paper, Dr. Grantley W. Taylor described the different types of Colles's fracture. Seventy-five per cent are the ordinary type, and in my estimation, their care is very simple. It is the comminuted types, which disturb the integrity of the radio-ulnar joint, in which poor results are obtained. I have seen cases in which the comminuted fractures have been well reduced that have gone on to a poor end result because they were taken care of in the ordinary routine manner. For this reason, I try to get the intern to de-

scribe the fracture in an anatomic fashion, and in that way the man handling it afterward knows with what he is dealing, and whether or not a case may need the necessary protracted fixation and to be kept up in flexion and pronation longer than the average case.

Haggard, in a rather good paper on this subject, advocated prolonged fixation. It was not clear to everyone what he was driving at, but I think it was at complicated types.

In treating these fractures, I tell my men to be sure to reduce the radial end and then pay attention to the ulna, which is the chief point after the radial fracture is reduced. The position we generally use is pronation flex-

FIGURE 6.

*These films show poor and incomplete reduction; the hand was flexed, but the radial fragment was still displaced and rotated backward.*

tion, attention being paid to the ulna, getting good deviation and keeping the ulna up and in.

Dr. PIERCE H. LEAVITT (Brockton, Massachusetts): The subject of Colles's fracture is still a controversial one. Surgeons were fighting over it in the good old days, and they are still fighting about it; there is still not enough emphasis on proper attack.

If a patient with gall-bladder disease or a goiter becomes worse, it is usually accepted by relatives and friends that these are serious cases and that the patients do not do very well, and the matter is ended. A Colles's fracture, however, especially with those of us who

meet it every two or three weeks of our lives, is a walking advertisement and not a very good one, if things do not go well.

Out in the country, where we meet the young lads who have come out of the big hospitals where they have had their training, we find a rather poor job done on Colles's fractures. The first thing seems to be that they lack the

FIGURE 7.

*In this case, excellent reduction was obtained; note that both films are true lateral views.*

courage to go ahead and take hold of the fracture and reduce it. They take it in hand, fool around a bit and put splints on and get somebody to take an x-ray film, and in six or eight weeks, the case drops into the hospital and the fracture is incompletely reduced.

I think more instruction should be given to the interns on nonfracture services; it should be emphasized that a Colles's fracture is a very grave thing and that it takes a definite amount of skill to handle one properly, and they should be carefully instructed on how to do so. There is a tendency for the intern to call up and say, "There is a Colles's fracture in," and the visiting man says, "All right, go ahead and fix it up"; they do it and get away with it in about 75 per cent of the cases, but the remaining 25 per cent are poorly done. I should put up a plea, being out in the country, for more careful, really severe, instruction and caution to the young lads in the handling of what everybody calls a simple fracture but to my mind is not.

DR. JAMES B. WOODMAN (Franklin, New Hampshire): I should like to ask Dr. Sever if he ever uses local anesthesia — novocain — in the reduction of Colles's fracture.

It has been my observation that these fractures are largely impacted and that complete relaxation makes it very much easier to reduce the fracture and get it where it will stay; it seems to me that the majority, after once being fully and completely reduced, have a tendency to stay reduced, although there are some that do not.

I used a local anesthetic once and got away with it, in an old lady. I did not wish to give her anything more than a local anesthetic.

DR. EZRA JONES (Manchester, New Hampshire): Dr. Sever has very well covered the subject of the usual type of Colles's fracture, and brought out the interesting points: proper forward angulation of the articular surface of the lower end of the radius and proper x-ray films. I thought it might be of interest to report two cases of an unusual type of this fracture, the reverse Colles's or Smith type. This, as you know, is very difficult to hold after reduction.

In one of these, when the patient came to the hospital, the fracture was reduced and placed in flexion, as the ordinary Colles's fracture is. There was a marked deformity two days later. After the next reduction, it was placed in moderate dorsiflexion. This resulted in a forward angulation of the lower fragments. After the next attempt, reduction was accomplished, and a cast was applied with the forearm and hand at 120°, but deformity resulted. Then it was decided that an open reduction was necessary.

This time, an incision was made over the dorsum of the forearm, and a screw was placed from the shaft down into the lower end. This gave a satisfactory result and, I believe, is an excellent way to hold this particular type of fracture.

DR. SEVER (closing): I used a local anesthetic once, at the suggestion of Dr. Robert Carruthers, of Cincinnati, who used to come to Boston occasionally. He and his son are very great advocates of local anesthesia in the reduction of fractures of all types. In this one case, a fractured wrist, I did not use novocain enough to anesthetize the area completely and I did not succeed in doing what I wanted to very comfortably. I did not like the method, and I have never used it in the reduction of a Colles's fracture since.

I use gas and oxygen or pentothal sodium, which is very simple and very easy, and in that way one can obtain sufficiently long anesthesia to do anything that one chooses.

I was very much interested in Dr. Jones's cases of reverse Colles's or Smith fracture, because I have never seen one. I have been looking for one for a long time, and here he shows up with two.

There was a very interesting paper, during the last year, in the *Journal of the American Medical Association*, on Smith fractures, in which the authors said that no case of reverse Colles's fracture could be held, or satisfactorily reduced and held, without an open reduction and fixation by some means or other. After hearing Dr. Jones's cases, I think that is probably quite right.

I do believe that we should make an effort to see that the x-ray technicians take true lateral views and insist on it, or even go and be present when the films are taken, and then make adequate measurements of the joint angles. It is a simple and satisfactory procedure, and one knows where one stands.

## ESSENTIAL DYSMENORRHEA\*

MAURICE FREMONT-SMITH, MD†

BOSTON

**E**SSENTIAL dysmenorrhea is a medical enigma, and the last sixty years have done little to solve this problem. In 1879, Dr J. M. Duncan, of St Bartholomews, discussed both the etiology and treatment of this disorder in terms almost identical with those in current use today.

The condition, although not serious in itself, may result in severe economic, social and psychologic handicapping of a young woman forced to look forward month after month to hours or days of regularly recurring pain and periodic disorganization of life. Small wonder that some women fear and resent their function as women and pass on to their adolescent daughters a distorted attitude toward the specific biologic function of womanhood.

It is to point out how little is known concerning the pathogenesis of dysmenorrhea that this paper is presented. Some recent investigative work is reviewed, contradictory experimental conclusions are presented, and the consequent confusion in rationale of treatment is discussed.

The onset of dysmenorrhea may coincide with the menarche or may first appear after months (even a few years) of painless menstruation. The pain, sometimes severe, crampy and usually suprapubic (occasionally with radiation to the back and thighs), may begin a few hours before and continue through the period, or twenty-four to forty-eight hours previously, ceasing with the appearance of active bleeding. Nausea and prostration are not infrequent.

Pregnancy usually (although not always) cures the condition; dilatation of the cervix gives relief, sometimes permanent, and presacral neurectomy eliminates pain (with an occasional failure and an occasional recurrence). Scores of remedies, some of physiologic potency, many inert, have given temporary relief.

Numerous theories have been offered in explanation of this condition.

## MECHANICAL THEORIES

For years, *cervical obstruction* was believed to be the cause of dysmenorrhea, and this hypothesis was sustained by the fact that dilatation was so frequently followed by relief. It is now recognized that, although a rare case of menstrual pain is due to cervical obstruction, such pain is not, strictly speaking, essential dysmenorrhea. In essential dysmenorrhea, the cervix is often soft and patu-

lous.<sup>1,2</sup> Why relief follows dilatation is not understood — paralysis of parasympathetic nerve endings in the cervix has been suggested. The degree and duration of relief is apparently related to the degree of dilatation obtained and the length of time it is maintained. Such relief rarely persists over six months, after which pain frequently returns at its previous level of intensity. The fact that even temporary relief is obtained after cervical dilatation, however, focuses attention on the cervix as a possible source of pain in this condition.

*Hypoplasia of the uterus* is present in some women who experience pain with the periods,<sup>2</sup> and long continued estrin therapy has lessened, but not cured, dysmenorrhea in a few cases.<sup>3</sup> Meigs<sup>4</sup> finds soft and atonic, as well as small, firm and anteverted, uteri in women with this disorder. He has noted many in whom the uterus is normal in size and consistence. The rhythm, ovulation and ability to bear children in women suffering from dysmenorrhea are characteristically normal.

*Presacral neuritis* has been considered a cause of dysmenorrhea. Davis<sup>5</sup> states:

in the majority of cases of severe spasmodic dysmenorrhea the peripheral sympathetic nerves of the uterus — as represented by the presacral nerve — are pathologically altered in some degree. This alteration is in the direction of a subacute or chronic neuritis, and manifests itself in widespread degeneration of the ganglion cells, interstitial infiltration, and the other changes described in detail above.

Such changes were found in over 70 per cent of his cases.

*Psychologic factors* are of undoubted importance in the etiology of dysmenorrhea.† Novak and Harnik<sup>6</sup> believe that all cases are explainable on the basis of psychic trauma. These authors report 168 cases treated by psychotherapy, with complete relief in 71 and improvement in 89. Others consider a lowered psychologic threshold responsible for dysmenorrhea, thus, stimuli of normal intensity, originating in the uterus, are interpreted, at the psychic level, as pain.<sup>7</sup>

That the pain of dysmenorrhea is in some way associated with *contractions of the uterine muscle* has been postulated on the following evidence: the pain is like that of uterine colic, it is described as identical with the pain of abortion by women who have experienced both, afterpains mimic the cramps of dysmenorrhea; during dysmenorrhea, the

\*Presented in part at the annual meeting of the American Clinical and Obstetrical Association, Skytop, Pennsylvania, October 17, 1941.  
†F. M. Smith, M.D., in Medicine, Harvard Medical School, associate physician at Massachusetts General Hospital.

‡A strong argument for a psychologic factor in dysmenorrhea is the response of patients to suggestion. Temporary relief follows almost every type of treatment with substances frequently contradictory in physiologic activity or else physiologically inert.

blood has been reported to leave the body in gushes<sup>5</sup>; and introduction of a sound into the uterine cavity produces identical pain.

Contradictory evidence exists, however, concerning the type of uterine motility obtaining throughout the normal menstrual cycle, and the causal relation between uterine contraction and pain. In the monkey<sup>8</sup> and, according to Dickinson,<sup>9</sup> in human beings, the greatest activity in the uterus and tubes occurs just prior to ovulation (in the normally menstruating woman between the fourteenth and sixteenth days of the cycle). With or soon after ovulation, these movements progressively decrease, and the latter part of the cycle is characterized by quiescence, persisting during corpus-luteum activity. During menstruation in human beings, Dickinson noted (by rectal palpation) only moderate contractility of the uterus—"never reaching an intensity comparable to that observed at the mid-interval."

Knaus<sup>10</sup> filled the cavity of the uterus with sterile oil and registered the changes in uterine pressure on a kymograph attached to an insufflator placed in the cervix. He found rhythmic contractions present during the first fourteen days of the cycle; during this period, the uterus responded by contraction to the intravenous injection of preparations of the posterior pituitary gland. From the sixteenth day to just before menstruation, spontaneous contractions were absent, and the uterus failed to contract following the intravenous injection of posterior pituitary extract. Knaus believed that the date of ovulation could be determined by the change in uterine response to pituitary extract.

However, Moir,<sup>11</sup> using the intrauterine balloon method, noted that myometrial activity was greater during the first and second days of menstruation than in any other portion of the cycle. When pain was present, the degree of uterine contraction roughly paralleled the intensity of discomfort experienced. In the presence of pain, he invariably found frequent and irregular contractions, during which intrauterine pressures of 120 mm. of mercury or more were observed. At the height of the cramp in many patients, the intrauterine pressure "exceeded by a considerable margin the systolic [?] brachial] blood pressure." Pain was experienced as the contraction neared its acme, but "tended to continue until the uterus was completely relaxed, and even then did not always cease at once." Moir reasoned that pain might be due, not to the uterine spasm as such, but to a diminution of blood flow during contractions, resulting in local ischemia of the myometrium. He suggested that the cramps were caused by a mechanism similar to that productive of pain in angina pectoris.

Other observations, however, cast doubt on a necessary relation between cramps and simultaneous uterine contractions. Falls et al.<sup>12</sup> stated that progesterin, given on the seventh day of the puerperium, effectively inhibited the uterine contractions associated with afterpains. Lubin, Clarke and Reynolds,<sup>13</sup> on the other hand, showed that although progesterin relieved the pains in every case in their series, the duration and frequency of contractions were not significantly altered. In cases in which lessening of amplitude of contraction occurred, relief of pain preceded recognizable changes in the height of contractions. Their conclusion was that "relief from after pains is not necessarily associated with striking changes in uterine motility."

Lackner, Krohn and Soskin<sup>2</sup> obtained complete relief of pain in 8 of 10 patients by endocrine treatment given during attacks of dysmenorrhea. In 5, relief followed progesterone therapy; in 3, progesterone was ineffective, and the pain was relieved following estrin. Two patients obtained no benefit from either preparation. Moreover, these authors, using the intrauterine balloon method, reported:

At least two of the women who obtained relief from progesterone showed no diminution in the size of their uterine contractions at the time their pain was completely relieved. The other three cases did show reduction in uterine motility, but relief occurred without amounts of progesterone necessary to cause demonstrable decrease in uterine contractions.

This work failed to establish the therapeutic value of progesterone in dysmenorrhea, and cast doubt on the hypothesis relating pain to uterine contractions per se.

Wilson and Kurzrok<sup>14</sup> confirmed Moir's observation that maximal contractions occur not just prior to ovulation but at the onset and during the early phase of menstrual flow. They found that the follicular phase was characterized by high tonus and small, rapid uterine contractions, and the luteal phase by lower tonus and slow contractions. They stated that "contractions of maximum intensity appear precisely when dysmenorrhea occurs." However, examination of seventy-two tracings (intrauterine balloon) from 14 patients with dysmenorrhea revealed "no significant variation in either tonus, rate or amplitude," as contrasted with three hundred and fifty-one tracings in 29 normal controls. They stressed the fact that only patients who had ovulated and showed a secretory endometrium could have essential dysmenorrhea.\*

Finally, Wilson and Kurzrok,<sup>7</sup> in 1940, studying 29 cases of dysmenorrhea by the intrauterine bal-

\*A woman with primary amenorrhea in whom cyclical bleeding was produced at regular intervals by the administration of estrin had painless periods. When progesterone was added to produce a secretory endometrium, the period was for the first time accompanied by pain.

loon procedure, failed to confirm Moir's finding that menstrual cramps coincided with unusually strong contractions of the uterus. Although dysmenorrhea was present, no apparent alteration from the normal myometrial motility was found. In each case in which pressures were recorded during cramps, the amplitudes were well below the level of the systolic pressure. In 1 patient, pituitary extract brought about an intrauterine pressure exceeding 120 mm., but no pain was experienced. If pain was already present, pituitary extract increased it, and uniformly caused a rise in tonus and an increase in amplitude and frequency of contraction. The authors reported one experiment in which the balloon was introduced into the uterus during dysmenorrhea; large contractions, typical of early menstruation, were observed. Later, the balloon was expelled. On its immediate reintroduction, no pain was experienced, but "except for a slight reduction in tonus [usual with introduction of a bag], there was no significant alteration in the type of contraction." Kurzrok believes, therefore, that "dysmenorrhea may be regarded as a disorder in which *normal* [italics mine] uterine contractions, during the phase of maximum amplitude, reach consciousness."

In summary, the following statements express these contradictory opinions concerning uterine physiology: uterine activity is greatest just prior to ovulation; the strongest uterine contractions occur at onset of menstruation; painful menstruation is accompanied by excessively strong contractions, resulting in high intrauterine pressures; progesterone relieves afterpain without simultaneously inhibiting contractions; there is no relation between cramps and the strength of uterine contractions or the height of intrauterine pressures; and dysmenorrhea does not occur in the absence of a secretory endometrium.

#### ENDOCRINE THEORIES

If the above observations are not in agreement regarding the physical mechanism of pain production, agreement is even less evident in the several endocrine theories proposed to explain dysmenorrhea. Fluhmann<sup>15</sup> lists the following current hypotheses: deficiency of estrin, excess of estrin, lack of progesterone, excess of progesterone, thyrotoxicosis, hypoglycemia and calcium deficiency. He remarks that dysmenorrhea may have no relation to a disturbed endocrine balance.

The various theories are not considered in this study except so far as they concern observations made in the Ovarian Dysfunction Clinic of the Massachusetts General Hospital.

Twenty-five cases of essential dysmenorrhea treated with estradiol benzoate were reported from this clinic in 1940 by Sturgis and Albright.<sup>3</sup> These

authors observed, confirming Kurzrok's findings, that ovulation during the preceding cycle was a prerequisite for dysmenorrhea. They demonstrated that by correctly timed administration of a potent estrogen, which acted presumably to inhibit the pituitary follicle-stimulating hormone and thus suppressed ovulation, painless bleeding could be consistently substituted for a painful period, and that such substitution could be continued over many months.

Although endometrial biopsy directly before a painful period invariably showed the normal secretory pattern, a proliferative endometrium was found prior to bleeding in every case in which a painless menstrual period had been induced by the administration of estrogens. Cramps could be induced in patients experiencing painless (anovulatory) bleeding by the administration of sufficient amounts of progesterone.

Since the publication of Sturgis and Albright's report, these observations have been verified and extended. Other estrogens, such as stilbestrol and estradiol dipropionate, have been substituted for estradiol benzoate, with identical results. In a few cases, estrogens given during the last two weeks of the cycle have brought about diminution—but in no case elimination—of cramps. Estrin therapy given approximately every other month over long periods (three years) has not, except in a few cases, brought about improvement in dysmenorrhea after therapy has been stopped. Progestin given to patients with dysmenorrhea during the week preceding the flow has generally increased pain at the subsequent period.

No satisfactory treatment for dysmenorrhea has been developed. Relief may be obtained by suppression of ovulation and production of conveniently timed anovulatory bleeding. As soon as normal menstruation, including ovulation, is resumed, dysmenorrhea recurs.\*

In a regular twenty-eight-day cycle, pituitary action may be consistently inhibited,—that is, ovulation may be suppressed,—and estrin-withdrawal bleeding, which is invariably painless, may be produced at about the usual time of the next expected period by one of the following procedures: about 15 mg. of estradiol benzoate intramuscularly on the sixth day following onset of the period, and every third day thereafter to a total of six doses; 1 mg. of diethyl stilbestrol orally on the sixth day after onset, and daily over a total period of twenty days; and 10 mg. of estradiol dipropionate intramuscularly on the sixth and sixteenth days following the onset of the period. If the

\*That pituitary function may be inhibited over long periods, with immediate resumption of activity after the inhibiting influence is withdrawn, is evidenced by cases of granulosa cell tumor and arrhenoblastoma. Following removal of such tumors, normal ovulatory periods are resumed.

cycle is other than twenty-eight days, estrin treatment, to repress ovulation, should be started on the twenty-second day before the next expected period.

### DISCUSSION

Contractions of the uterus may be painless—even strong contractions, as at the onset of labor or, in a painless phase, following the administration of pituitary extract. In dysmenorrhea, however, considerable evidence of a time relation between uterine contractions and the occurrence of pain has been presented. Under certain circumstances, particularly when pituitary extract is given during a painful phase, both contractions and pain are increased simultaneously. For the existence of such a painful phase, the effect of progesterone is apparently necessary.

Therefore, the following tentative conclusions seem warranted: the pain of dysmenorrhea does not occur in the absence of active uterine contractions; and one or more secondary factors must be present if pain is to occur. If this is true, treatment of the disorder could be effective either by causing diminution of uterine contractions or by influencing this unknown secondary factor. One may thus regard the contraction as the precipitating and some other (? endocrine or circulatory) factor as the predisposing cause of dysmenorrhea.

### SUMMARY

Theories of the causation of dysmenorrhea are reviewed, contradictory observations on normal uterine physiology are presented, and the present status of treatment is discussed.

## MEDICAL PROGRESS

### LABORATORY AIDS IN THE DIAGNOSIS AND PROGNOSIS OF HEART DISEASE\*

LAURENCE B. ELLIS, M.D.†

BOSTON

THE average cardiac patient can be diagnosed with accuracy and treated properly and effectively with little or no assistance from the laboratory. Many patients, however, are not average and can be adequately evaluated only with the help of such laboratory aids, and since the total number of persons with real or suspected heart disease is very large, the total number of patients requiring such study will be very considerable. In general, laboratory tests of value in cardiology can be divided into those that give information concerning the pres-

ence of heart disease or one of its manifestations, and those that are useful in estimating the functional capacity of the heart. However, just as it is impossible to divide clinical symptoms or physical signs into those that are purely diagnostic and solely prognostic, so the two types of laboratory procedures often overlap. Moreover, some tests are sufficiently simple, accurate and helpful to be part of the armamentarium of the general practitioner; some are of established practical value but are complex or require elaborate apparatus so that they fall into the province of the specialist or the large clinic; and finally there are tests that may be usefully employed in research in cardiologic problems but have not yet become applicable in clinical practice. Every physician should know, to some extent at least, of the tests that fall into each group, and their bounds of usefulness.

Reprints of articles in this series are not available for distribution, but the articles will be published in book form. The current volume is *Medical Progress: Annual, 1940* (Springfield, Illinois: Charles C Thomas Company, 1941. \$4.00).

### Valuable Laboratory Tests in General Practice

**Electrocardiogram** When one thinks of a laboratory test in the diagnosis of heart disease, the first that comes to mind is undoubtedly the electrocardiogram. The application of the electrocardiogram to the general practice of medicine was dealt with in a previous progress report.<sup>1</sup> Since then, little that is new of importance to the general practitioner has been published, although a good summary of its value by Marvin<sup>2</sup> has appeared, as well as several good new textbooks, notably those by Graybiel and White<sup>3</sup> and Katz,<sup>4</sup> and new editions of older but standard texts, such as those by Ashman and Hull,<sup>5</sup> and Pardee.<sup>6</sup>

The place of the electrocardiogram in general practice should be evaluated in the light of the following facts. The electrocardiogram is an instrument for the measuring of changes in electrical potential set up in the heart by the spread of the excitatory impulse or the contraction of the heart muscle; it measures this and nothing else. It gives valuable information regarding arrhythmias and heart block; it is often of great diagnostic help in cases of myocardial infarction and frequently shows changes indicative of disease in the heart that are useful when assessed against the clinical findings. It gives no information directly of the presence of valvular disease and, hence, is of little help in the interpretation of murmurs. It reveals nothing regarding the presence or absence of myocardial failure, either congestive or anginal. With proper appreciation of the bounds of its usefulness, and adequate training in the interpretation of the tracings, it is a valuable and occasionally essential aid in the handling of cardiac patients. Unfortunately, there is at present a tendency on the part of some physicians not fully trained in electrocardiography to exploit it beyond its limitations, with the result that on occasion much harm is done from wrong diagnosis and ill-advised therapy based on the misinterpretation of electrocardiograms.

**Cardiac roentgenography.** The x-ray offers the best method of studying the size and shape of the heart and its various chambers and of the great vessels. Although an anteroposterior roentgenogram with the tube at a distance of 6 or 7 feet, to minimize distortion, is usually adequate, more information as a rule can be gained from fluoroscopic examination, which gives a dynamic picture of the movement of the various parts of the heart and great vessels, and more easily permits study in the oblique and lateral positions. Such study is particularly useful in estimating enlargement of the aorta, the left auricle or the right ventricle. Although no test is highly reliable, fluoroscopy is the most helpful method of detecting early syphilitic aortitis. The diagnosis of mitral stenosis can sometimes be confirmed by this procedure when

the results of physical examination are equivocal.<sup>7</sup> It has been claimed that myocardial infarctions can be detected by such examination<sup>8</sup>; however, few roentgenologists or cardiologists are sufficiently skilled in fluoroscopy to diagnose such lesions with certainty in the absence of other clinical evidence. Just as with electrocardiography, there is an unfortunate tendency for some to exaggerate the role of roentgenology in cardiac diagnosis.

Recently, Robb and Steinberg<sup>9</sup> have perfected a method, which had been previously employed, for the visualization of the heart and great vessels by the sudden introduction into the circulation of a large amount of opaque material (Diodrast) and the recording by x-ray photographs taken at appropriate times. This method has at times proved to be of great help, especially in the differential diagnosis of mediastinal lesions, but it is a procedure whose use is limited, owing to the great technical dexterity and experience required and to the fact that its safety has not yet been completely established.

**Vital capacity.** Ever since the demonstration by Peabody and his associates in 1917 of a reduced vital capacity of the lungs in congestive heart failure, this test, being simple and easy to carry out, has been widely employed. Unfortunately, it has a limited application in the diagnosis of individual patients. Although it is quite true that the vital capacity is reduced in early heart failure, the limits of normal are so wide that minor reductions may not be detectable; and, moreover, conditions that frequently enter into the differential diagnosis of heart failure, such as chronic pulmonary disease, often also involve a reduction in vital capacity. Occasionally, the demonstration of a normal vital capacity in a person who complains of great difficulty in breathing is evidence in favor of the functional nature of the complaint, but such patients with neurocirculatory asthenia not uncommonly register low vital capacities, possibly because of an inability properly to perform the respiratory maneuver involved in the test.

This test is most helpful in following the progress of individual patients with known heart disease, since an increase or decrease in the vital capacity is often a useful index of improvement or regression. However, the patient's own statements regarding the degree of dyspnea encountered in his daily activities are usually fully as accurate a guide of his condition.

**Velocity of blood flow.** The principle of this procedure was first applied on a large scale by Blumgart, who, in 1927, with the collaboration of Yens, devised the radioactive method. He<sup>10</sup> subsequently explored its significance, which he reported in a series of papers, in the preparation of most of which the late Dr. Soma Weiss was asso-

ciated. When a substance is introduced into a peripheral vein, it passes from there to the right heart, through the pulmonary circulation back to the left heart and out into the systemic arteries. If the arrival of such a substance, either in the pulmonary vessels or at some point in the systemic arterial system, can be determined, the speed of blood from the point of injection to the end point can be easily measured and related to normal standards obtained with the same technic. If the cross-sectional area of the vascular bed, especially in the lungs, does not change, changes in blood velocity will vary directly with changes in the output of the heart. There are, however, frequent changes in the cross-sectional diameter of the vascular bed, with or without alterations in the cardiac output. In heart failure, the blood velocity (or circulation time) is, with rare exceptions, prolonged owing either to pulmonary and peripheral stasis, with engorgement and widening of the blood vessels, or to a reduced cardiac output, or to both. There are rare cases of heart disease (hyperthyroid heart, severe anemia and, occasionally, beriberi) in which the circulation time may actually be fast even in the presence of congestive failure, because of peripheral vasodilatation or increase in cardiac output. In chronic pulmonary disease, the blood velocity is usually normal.

The chief practical value of blood-velocity determinations is in cases in which the cause of dyspnea (pulmonary or cardiac) is uncertain.<sup>11</sup> This problem most commonly arises in elderly people in whom the dyspnea may be due either to a failing arteriosclerotic heart or to senile emphysema and chronic bronchitis. In the former, the blood velocity may be prolonged; in the latter it is unchanged. Occasionally, the test may give helpful evidence regarding one of the rare types of heart disease with a rapid circulation mentioned above.

Finally, the test may be useful in detecting abnormal arterial shunts in congenital heart disease.<sup>12</sup> By the selection of appropriate substances, the appearance time can be determined either in the pulmonary vessels or in the systemic arteries after the passage of the pulmonary circulation. Naturally, the second involves a longer interval than the first. If, however, there is a right-to-left shunt in the heart, as with a patent interventricular septum with concomitant pulmonary stenosis (tetralogy of Fallot), the appearance time in the peripheral arteries may be as short as that to the lungs, owing to the short circuit.

Many substances are employed for the measurement of blood velocity, and the appearance time of each is registered in its own way — by quickened respirations, flushing, distinctive taste or burning sensation of the tongue, cough or the characteristic

odor of the breath. Radioactive material, sodium cyanide, decholin, calcium gluconate, saccharin and so forth are used to measure the circulation time through the lungs and to the systemic circulation, and ether and paraldehyde are employed as measures of the arm-to-lung velocity. Several articles summarizing the application and value of these various tests are available.<sup>10, 13</sup>

*Venous pressure.* The term "venous pressure" as applied to the study of heart disease refers to the pressure in the right auricle, which is obtained by determination of the pressure in a large peripheral vein and subtraction of whatever hydrostatic pressure difference there may be between the level of the vein and the estimated position of the right auricle.

There are two methods of estimating venous pressure, the direct and the indirect. One performs the indirect method by sealing a small transparent capsule over a superficial vein, usually of the dorsum of the hand, and increasing the air pressure within the capsule until the vein begins to collapse.<sup>14</sup> Although the procedure may still have some application in research, it is more involved, requires more experience and is less accurate than the direct method, which has largely supplanted it in clinical practice.

This latter method simply requires the cannulization of a vein with a large bore needle connected with a manometer filled with saline solution; one then relates the height of the column of fluid in the manometer to the level of the right auricle, as estimated from the dorsal<sup>15</sup> or ventral<sup>16</sup> surface of the chest.

In the majority of cases of heart failure, such a determination of venous pressure is unnecessary, since the diagnosis is sufficiently clear, or because a fairly accurate clinical estimate of the venous pressure can be obtained from observation of the level at which the external jugular veins collapse as the patient is gradually raised from a supine to a semi-recumbent position. However, it is occasionally difficult or impossible to tell whether edema is of cardiac origin or due to a noncardiac condition, such as portal or other venous obstruction. In such a case, the determination of venous pressure may be helpful, especially if carried out simultaneously above and below the suspected site of the obstruction — as in the cubital and femoral veins if obstruction of either the superior or inferior vena cava is suspected. Venous-pressure measurements may also be useful in following the progress of cardiac tamponade and as a guide for pericardial tapping.

*Arterial blood pressure.* The measurement of the arterial blood pressure is so universally employed that one hardly thinks of it as a laboratory

edure. However, certain refinements in the ng of blood pressure, although important, are oo easily overlooked, and every doctor would sell to review these as set forth in the state-<sup>17</sup> issued by the American Heart Association. raphic methods of recording blood pressure available but have not proved of great value imical practice.

**Hemoglobin determination.** No examination of tent suspected of heart disease is adequate out a hemoglobin determination to discover xistence of anemia, or rarely of polycythemia, ry or secondary. A hemoglobin determina-<sup>18</sup> carried out by an accurate method is sufficient, not necessary to perform a red-cell count is the hemoglobin content is abnormal<sup>19</sup> emia places a burden on the circulation in ways. On the one hand, diminution in the<sup>20</sup> globin, and hence of the oxygen carrying r of the blood, results in impaired nutrition<sup>21</sup> the heart because of relative anoxia of the<sup>22</sup> ardiu; on the other hand, the heart of the<sup>23</sup> ne person attempts to compensate for the low<sup>24</sup> en capacity of the blood by increasing its out<sup>25</sup> and hence the work of the heart is increased<sup>26</sup> y, anemia alone leads to heart failure, much<sup>27</sup> commonly, anemia of mild or moderate de-<sup>28</sup> exists as an aggravating burden in a person<sup>29</sup> organic heart disease. Such anemia can<sup>30</sup> ly be satisfactorily treated, the added burden<sup>31</sup> ved and the patient's cardiac status thus im-<sup>32</sup> d.

ce the symptoms and signs of severe anemia<sup>33</sup> some resemblance to those of heart failure,<sup>34</sup> too frequently patients with normal hearts<sup>35</sup> ing from anemia are wrongly treated as cir-<sup>36</sup> pitients. These patients may complain of<sup>37</sup> hlessness, fatigue and dependent edema. They<sup>38</sup> have enlarged hearts with systolic and rarely<sup>39</sup> clic murmurs, and may exhibit electrocardio-<sup>40</sup> ic abnormalities. Such mistaken diagnoses<sup>41</sup> usually be easily avoided if proper examin-<sup>42</sup> of the blood is made.

**Sedimentation rate and leukocyte count.** Both<sup>43</sup> procedures have a useful place in cardiology,<sup>44</sup> ally when patients with active rheumatic<sup>45</sup> or myocardial infarction are followed. In<sup>46</sup> : rheumatic fever, either test is contributory<sup>47</sup> nce in favor of activity.<sup>48</sup> The sedimentation<sup>49</sup> is likely to be elevated for a much longer<sup>50</sup> than the leukocyte count and hence is a<sup>51</sup> : guide of persistence of the infection,<sup>52</sup> ough neither test is infallible. In myocardial<sup>53</sup> tion, the leukocyte count is often elevated<sup>54</sup> n the first twenty-four to forty-eight hours,<sup>55</sup> e time of the febrile response that generally<sup>56</sup> s, and may reach 20,000 to 25,000. Within<sup>57</sup> days, it usually returns to normal. The sedi-

mentation rate does not begin to rise, as a rule,<sup>58</sup> for several days after the onset but continues<sup>59</sup> elevated in most cases throughout the healing<sup>60</sup> period—that is, about six weeks. It is the best<sup>61</sup> laboratory guide of healing in myocardial infar-<sup>62</sup> tion.<sup>63</sup>

**Blood nonprotein or urea nitrogen.** In cardio-<sup>64</sup> renal cases with organic renal insufficiency, in<sup>65</sup> marked heart failure when there is a depression of<sup>66</sup> renal function due to congestion, and in certain<sup>67</sup> patients who are dehydrated,—even occasionally<sup>68</sup> in the presence of edema,—azotemia may occur,<sup>69</sup> and its existence can be demonstrated by the find-<sup>70</sup> ing of an elevated blood urea nitrogen or non-<sup>71</sup> protein nitrogen. The toxic effect may contribute<sup>72</sup> to the heart damage and thus institute a vicious<sup>73</sup> circle. If this state of affairs is diagnosed, fre-<sup>74</sup> quently by the judicious administration of fluids,<sup>75</sup> much can be done to ameliorate it.

Tests that indicate early impairment of renal<sup>76</sup> function are often useful and provide guides to<sup>77</sup> the best management of certain difficult cases. A<sup>78</sup> simple test of this type, easily carried out in the<sup>79</sup> office or home, is the concentration test. If a<sup>80</sup> person can concentrate his urine to 1 020 or higher<sup>81</sup> after being deprived of water for fifteen to twenty-<sup>82</sup> four hours, his renal function is rarely greatly<sup>83</sup> impaired. If such a patient has, at the same time,<sup>84</sup> nitrogen retention, it is of extrarenal origin and<sup>85</sup> not due to renal insufficiency. Of course, if a<sup>86</sup> patient is edematous, and especially if he is in a<sup>87</sup> diuretic phase, it may be impossible to dehydrate<sup>88</sup> him sufficiently to obtain a concentrated urine sam-<sup>89</sup> ple, and under such circumstances the concentra-<sup>90</sup> tion test becomes of no help. Another renal-func-<sup>91</sup> tion test easily performed is the fractional phenol-<sup>92</sup> sulfonphthalein excretion test.<sup>93</sup> More compli-<sup>94</sup> cated, but more accurately quantitative, are the<sup>95</sup> various clearance tests, in which the rate of ex-<sup>96</sup> cretion of substances such as urea, creatinine,<sup>97</sup> inulin, Diodrast and glucose are determined.<sup>98</sup>

**Urine and blood sugar.** Since diabetes is so<sup>99</sup> commonly associated with degenerative vascular<sup>100</sup> disease, many cardiac patients also have diabetes.<sup>101</sup> The proper regulation of the diabetic state is an<sup>102</sup> important element in the therapy of heart disease.<sup>103</sup> Therefore, the urine of every cardiac patient<sup>104</sup> should be carefully and often repeatedly examined<sup>105</sup> for sugar, and if any sugar is found in the urine,<sup>106</sup> studies of the blood sugar level should be under-<sup>107</sup> taken.

**Serologic tests for syphilis.** It is universally<sup>108</sup> agreed that no clinical examination is complete<sup>109</sup> without a serologic test for syphilis, especially in<sup>110</sup> cardiac diagnosis, since a positive test may be the<sup>111</sup> only clue leading to a more extensive search for<sup>112</sup> early aortitis. A negative test cannot, however, be<sup>113</sup> considered proof of the absence of cardiovascular

syphilis. The reported incidence of patients with such involvement who have positive blood Wassermann reactions varies from 65 to 95 per cent. McDermott et al.<sup>23</sup> found only 2.2 per cent of a series of 135 patients with syphilitic aortitis who did not have either a positive Wassermann or a previous history of syphilitic infection or anti-syphilitic treatment. The number in whom the blood Hinton reaction, or a similar more delicate test, is negative is probably less, although statistical studies are not yet available.

*Plasma proteins.* The significance of plasma proteins has been fully discussed in other articles of this series.<sup>24, 25</sup> Plasma proteins, and especially plasma albumin, may be lowered in heart failure for any one or a combination of five reasons: deficient protein in the diet; deficient absorption of protein from the gastrointestinal tract; impaired formation of plasma albumin in the liver or elsewhere; loss of protein through the kidneys or in serous effusion; and hydremia. A low plasma protein, with resultant low plasma osmotic pressure, may therefore become a significant contributory factor in the edema of heart failure, although it is not the primary causative factor. Whenever persistent edema in heart failure does not respond to the usual therapy, it is useful to have a determination made of the plasma proteins or, better yet, of the albumin and globulin fractions. If the total proteins fall below 5.0 to 5.5 gm. per 100 cc., or if the albumin falls below 2.5 gm., the edema is probably in part maintained by low osmotic pressure. Not infrequently, under such conditions, the feeding of a high-protein diet proves beneficial.

Plasma proteins can be determined by direct chemical means without great difficulty, and clinical laboratories are now usually equipped to perform such tests. A simple way of estimating the total plasma protein is by measurement of the plasma specific gravity, which varies directly with the protein content. Relatively inexpensive and simple apparatus for such measurement is available.

*Blood culture.* The chief occasion for carrying out this procedure is in cardiac patients in whom acute or subacute bacterial endocarditis is suspected. These conditions are not uncommon. Repeated positive blood cultures are the greatest aid to accurate diagnosis, and since modern chemotherapy has in some cases proved highly beneficial, the value of establishing the correct diagnosis as early as possible is evident. If necessary, it is comparatively easy to obtain the blood for culture under sterile precautions in the home, and most hospitals and state health departments

are equipped to carry out the necessary bacteriologic examinations.

*Basal metabolic rate.* In heart failure, the basal metabolic rate, as obtained by the usual technic, often elevated to levels that average about 10 per cent above normal but may reach more than 50 or 60 per cent.<sup>26</sup> In the presence of heart failure, therefore, these determinations are of negative value only in excluding hyperthyroidism. However, the test is frequently of advantage in the differential diagnosis of certain types of cardiac syndromes, notably hyperthyroidism and neurocirculatory asthenia or menopausal symptoms.

#### *Specialized Laboratory Tests of Clinical Value*

*Phonocardiography.* Increasingly, instruments are being made available for the graphic registration of heart sounds and murmurs. Doctors are turning to such devices hoping that they will tell them what the human ear cannot hear. As often happens, they frequently expect too much. Phonocardiography is a specialized technic, still highly experimental and, like electrocardiography, requires special training in interpretation. Phonocardiographic recording devices are of various types ranging from those registering vibrations as they are produced, irrespective of the degree in which they are perceived by the human ear, to those modified that they register the vibrations in approximately the same fashion as that appreciated by the human brain. These devices have a considerable usefulness in the experimental laboratory or in exact clinical exploration, particularly in the study of heart sounds. At present, their use in the interpretation of murmurs is limited. Recent articles by Johnston and Kline<sup>27</sup> and by Rappaport and Sprague<sup>28</sup> discuss at length the factors that govern auscultation and the registration of sounds, whereas the most complete work on the graphic registration of human heart sounds in normal and pathologic conditions is the book by Orian and Braun-Menendez.<sup>29</sup>

*Blood volume.* Estimations of the blood volume are made indirectly by injection into the bloodstream of something that is mixed in the plasma without being excreted or destroyed in appreciable amounts for some time. Thus, if the amount injected, the concentration in the plasma and the rate of disappearance of the substance from the blood are known, the total circulating plasma volume can be calculated and, since the hematocrit is known, the blood volume as well. Inert dyes have been employed for this purpose since the demonstration by Keith, Rowntree and Geraghty<sup>30</sup> that vital red could be successfully employed for the purpose. Carbon monoxide<sup>31</sup> has also been employed to compute the circulating cell volume.

Inaccuracies in the earlier methods prevented the obtaining of many clinical data, but in 1935, Gregersen et al.<sup>3,2</sup> developed an improved modification of the dye method using Evans blue. Since then, much valuable information concerning blood-volume change in heart failure, as well as in other states, has been forthcoming, in large part in publications by Gibson and his associates.<sup>2,3,14</sup> They have confirmed the fact that the blood volume may be increased in congestive heart failure, often to a very significant degree. Although, in theory, determinations of the blood volume should be helpful in indicating the existence or extent of myocardial failure, practically, the test is so complicated that it is as yet applicable only in the research laboratory.

### Research Tests

**Cardiac output.** For many years, determinations of the cardiac output in human beings have been made in normal and abnormal states. Most of these have been carried out indirectly by the application of the Fick principle or by the rate of absorption through the lungs of foreign gases.<sup>30</sup> The Fick principle states that if the oxygen or carbon dioxide contents of the arterial blood and the venous blood returning to the heart are known and if the total oxygen consumption or carbon dioxide excretion per minute is also measured, the rate of blood flow can be easily calculated. The oxygen and carbon dioxide contents of the arterial and venous bloods are estimated from the gaseous contents of air from the lungs, obtained by special respiratory maneuvers. More recently, variations of this method have been widely used whereby foreign gases, such as nitrous oxide,<sup>30</sup> acetylene<sup>37</sup> and ethylolide,<sup>38</sup> are employed. If the rate of absorption of such gases from the lungs into the arterial blood is calculated and compared with the rate of oxygen absorption and the total minute oxygen consumption, the cardiac output can be readily computed. Such methods, and in particular that employing acetylene, when properly applied give reliable results comparable to the cardiac output measured directly by the obtaining of blood samples by direct puncture of the right heart and of the arteries.<sup>30</sup>

Through the application of such methods for estimating cardiac output, very valuable information has been gained concerning the abnormal physiology in heart disease and in heart failure. However, these techniques are not of use in the clinic, they are too complicated and require great skill by the operator and co-operation and training by the subject. Moreover, unfortunately, the very condition that is most essential to study—congestive heart failure—is that in which this test can be applied with the greatest difficulty or not at all.

**Arterial oxygen saturation.** It is now a comparatively simple procedure to obtain samples of arterial blood, determine its oxygen content and capacity and thus calculate the percentage saturation. This may be of value in any condition in which arterial anoxemia is suspected. The clinical sign, cyanosis, is brought about by an increased amount of reduced hemoglobin in the blood as it flows through the vessels that give skin color—namely, the venules.

Cyanosis may result from any one or a combination of a number of causes. In cardiac disease, two main factors may be responsible: arterial anoxemia and peripheral stasis. Normally, the blood is oxygenated as it leaves the lungs, and hence the arterial blood is about 95 per cent saturated with oxygen. This high degree of arterial oxygen saturation may be reduced by pulmonary factors, acute or chronic, that interfere with aeration of the blood (as in pulmonary congestion or consolidation, marked emphysema or pulmonary vascular disease), or by abnormal communications that permit blood to pass from the right side of the heart directly to the left side (as in some types of congenital heart disease).

Peripheral stasis, which occurs in some cases of mitral stenosis and in chronic right-sided failure or in venous obstruction, leads to cyanosis because of the slow blood flow and the unusual degree of oxygen unsaturation of the venous blood. The hemoglobin content of the blood markedly affects the development of cyanosis. Since this sign is dependent on the absolute amount of reduced hemoglobin in the peripheral blood, cyanosis cannot occur in severe anemia even though the factors that would ordinarily lead to it are present. Conversely, in polycythemia, cyanosis is often present even with normal arterial saturation and blood flow. The determination of the degree of arterial oxygen saturation in patients with polycythemia is an important differential test, since such saturation is essentially normal in primary polycythemia, whereas it is reduced in secondary polycythemia. Thus, on many occasions the determination of the cause of cyanosis in a given case is essential, and in such cases the estimation of arterial oxygen saturation becomes a desirable and often even a necessary procedure. At present, not many laboratories, outside research institutions, are equipped to carry out such determinations, but they are not especially difficult and no doubt will have wider clinical application in the future.

\* \* \*

No examination of any cardiac patient should be considered adequate without the performance of at least a few simple clinical tests. These are determination of the arterial blood pressure, hemoglobin

content of the blood, a serologic test for syphilis and a routine urinalysis. An electrocardiogram and roentgenographic study of the heart, although desirable for complete evaluation of the case, can often be dispensed with, but on occasion such procedures become absolutely essential to a correct diagnosis. Other laboratory procedures are often useful and sometimes necessary.

## MASSACHUSETTS MEDICAL SOCIETY

## PROCEEDINGS OF THE COUNCIL

Special Meeting, April 15, 1942

A SPECIAL meeting of the Council of the Massachusetts Medical Society was held in John Ware Hall, Boston Medical Library, 8 Fenway, Boston, on Wednesday, April 15, 1942, at 10:30 a. m.

Dr. Frank R. Ober, president of the Massachusetts Medical Society, presided and Dr. Michael A. Tighe served as secretary. There were 189 councilors present (Appendix No. 1).

The record of the February 4, 1942 meeting of the Council, as published in the *New England Journal of Medicine*, issue of March 12, 1942, was offered by the Secretary, who moved its adoption. This motion was seconded by Dr. I. R. Jankelson, Norfolk, and carried by vote of the Council.

Dr. Ober announced that the purpose of this meeting was to give consideration to the report of the Committee on By-Laws, appointed as the result of the action of the Council at its stated meeting in October, 1941. The personnel of this committee is as follows: Dr. J. Harper Blaisdell, chairman; Dr. Carl Bearse; Dr. John Fallon; Dr. Albert A. Hornor; and Dr. Harold R. Kurth.

Dr. Ober requested that the members observe the following regulations in debate so as to assure accurate reporting of the proceedings:

1. Changes in the text which are to be presented to the Council must be by way of amendment to that text.
2. Amendments must be in writing.
3. Written reference must be made to the chapter, section, page and line or lines amended.
4. The name of the councilor offering the amendment must be attached to it.

The President further requested that each councilor participating in the debate announce his name and district.

Dr. J. Harper Blaisdell, Middlesex East, was introduced. Dr. Blaisdell, preliminary to offering the report of his committee, paid tribute to Dr. Richard Dutton of Middlesex East. He said that it was due to Dr. Dutton's inspiration that this work was initiated. He added that his committee had held fifteen meetings involving at least one hundred hours and that many of these hours had been spent in conference with the Executive Committee and the standing committees involved in the contemplated changes. He thanked Dr. and Mrs. Kurth, of Methuen, Dr. and Mrs. John Fallon, of Shrewsbury, and Dr. and Mrs. Tighe, of

Lowell, for their hospitality. He expressed the thanks of his committee to Dr. Ober and Dr. Tighe for their help.

He reported that the legal aspect of the by-laws to be presented had been passed on by counsel, in the person of Mr. E. L. Twomey, and that the English had been checked by Dr. Robert N. Nye, managing editor of the *New England Journal of Medicine*. He called the Council's attention to the fact that the committee's report had not been signed by Dr. Albert A. Hornor, of Suffolk. He added that he would not infringe on Dr. Hornor's privilege of offering his own reasons for not doing so.

Dr. Blaisdell explained that after the text had gone to print, the necessity for certain typographical and textual corrections became evident. He said that these corrections did not involve any change in principle. He asked for the unanimous consent of the Council to make the following changes in the text:

That lines 14, 15 and 16\* of Chapter I, Section 5, be deleted. (These lines represent a repetition of what appears in Section 10 of the same chapter.)

That in line 15 of Chapter I, Section 9, "Chapter VII, Section 9, and Chapter VIII, Section 1," be substituted for "Chapter VIII, Section 9."

That Section 11 of Chapter I, which reads as follows:

Section 11. Committees having under consideration the applications of former fellows (a) whose resignations have been requested by the Committee on Ethics and Discipline or (b) who have been deprived of fellowship under the terms of Section 9 shall consult with the Committee on Ethics and Discipline before reporting their recommendations to the Council.

be deleted, and that the following be substituted:

Section 11. Former fellows who desire to be readmitted following (a) resignations requested by the Committee on Ethics and Discipline or (b) who have been deprived of fellowship under the terms of Section 9 shall make application in writing addressed to the Council and sent to the Secretary.

Such applications shall be referred for investigation to the board of membership of the district society concerned, which shall report with recommendations to the Committee on Membership.

The board of membership of the district society concerned and the Committee on Membership shall consult with the Committee on Ethics and Discipline before recommendations are reported to the Council.

The Council may readmit former fellows so recommended.

\* "Lines," whenever mentioned, refer to the copy of the proposed by-laws published in the April 2 issue of the *Journal*.

That in line 27 of Chapter VI, Section 1, "Chapter VII, Section 9," be substituted for "Chapter VIII, Section 1."

That in line 19 of Chapter VIII, Section 1, "Chapter VII, Section 9," be substituted for "Chapter I, Section 10."

On motion of Dr. Blaisdell and a second by Dr. Hilbert F. Day, Middlesex South, the Council gave unanimous consent to these changes.

Dr. Blaisdell moved that the report of this committee be accepted. The motion was seconded by Dr. Harold G. Giddings, Middlesex South, and adopted by vote of the Council.

Dr. Blaisdell moved that the Council proceed to consider the proposed by-laws chapter by chapter and section by section. This motion was seconded by Dr. Lester M. Felton, Worcester, and carried by vote of the Council.

Dr. Ober, anticipating a possible need, appointed Dr. Edward M. Halligan, Middlesex East, and Dr. Leroy E. Parkins, Suffolk, tellers.

There was some discussion at this point as to procedure. In this discussion the following councilors participated: Dr. George D. Henderson, Hampden, Dr. Raymond A. McCarty, Middlesex South, and Dr. Blaisdell. It was finally agreed that the vote would first come on the adoption of the section as contained in the text before the Council and, in the event that this section was adopted, a motion should be offered for the deletion of the corresponding section in the by-laws as amended in 1941.

Dr. Blaisdell offered Chapter VII, Section 1, which reads as follows:

## CHAPTER VII

### COMMITTEES

*Section 1.* Reports of committees containing recommendations that may require prolonged consideration shall be sent in abstract to the Secretary, at least six weeks before their presentation to the Council, for consideration by the Executive Committee and for publication in the official journal.

Every committee, annually on or before December 10, shall forward, to the chairman of the Committee on Finance, an estimate of its expenses for the ensuing fiscal year, which shall show the purpose of any proposed expenditure of \$100 or more and a similar detailed statement of its expenditures for the current fiscal year to and including November 30 with an estimate of expenditures for the current month of December.

All bills of \$100 or more incurred by a committee shall be countersigned by a majority of said committee and forwarded to the President for his approval.

All bills less than \$100 incurred by a committee shall be countersigned by the chairman of said committee and forwarded to the President for his approval.

Every committee shall render a written report to the Council at least once a year.

Dr. Blaisdell, in commenting on this section, said that it provides first, time for review by the Execu-

tive Committee of such committee reports and their publication in the *Journal* in advance of the Council meetings, as may require the mature deliberation of the councilors. Secondly, it provides that bills of \$100 or over must have the signature of all the members of a given committee. Dr. Blaisdell moved the adoption of Chapter VII, Section 1. The motion was seconded by Dr. William H. Allen, Bristol North.

Dr. John Homans, Suffolk, said that there was some question in his mind as to the ability of the Finance Committee to observe the timetable which was involved in this section.

Dr. Allen G. Rice, Hampden, asked if the chairman of the Finance Committee had had opportunity to be heard on this section. The answer was in the affirmative. The question was demanded. The motion was passed by vote of the Council.

Dr. Blaisdell moved that Section 11 of Chapter VII of the by-laws as amended in 1941 be deleted. This motion was seconded by Dr. John Fallon, Worcester, and adopted by vote of the Council.

Dr. Blaisdell read Section 2 of Chapter VII, which is as follows:

### COMMITTEES ELECTED BY THE DISTRICTS

*Section 2.* The Executive Committee of the Council shall consist of the President, President-Elect, Vice-President, Secretary and Treasurer and a councilor from each district society, chosen as provided in Chapter III, Section 5.

The Executive Committee shall meet at the call of the President. It shall assist the President in preparing matters for consideration by the Council.

It shall act on all questions of retirement, resignation, remission of dues, deprivation of fellowship for arrears, reinstatement following deprivation of fellowship for arrears, and transfer of fellows from one district to another without change of legal residence.

The Executive Committee may appoint and dismiss the Executive Secretary.

It shall authorize or confirm action by the officers in emergency.

The Executive Committee shall perform such other duties as the Council may require.

Dr. Blaisdell said that this chapter divides the committees of the Society into two groups, those elected by district societies and standing committees. It refers to the Executive Committee certain routine matters which heretofore had consumed considerable of the Council's time. Dr. Blaisdell moved the adoption of this section. The motion was seconded by Dr. John J. Curley, Worcester North.

Dr. David Cheever, Suffolk, questioned the wisdom of transferring to the Executive Committee the functions now resting in the Council and expressed himself as not being in favor of such a transfer. He said, however, that he was open to persuasion.

Dr. Walter G. Phippen, Essex South, thought that this was a fair disposition of the matters referred to in the section. He added, however, that the Executive Committee should be required to report its acts, as they pertain to this section, to the Council.

There was much discussion along the same lines. Those participating were Dr. Fallon, Dr. Allen G. Rice, Hampden, Dr. Richard M. Smith, Suffolk, and Dr. G. Colket Caner, Suffolk.

Dr. Ober at this point observed that the Executive Committee had reported at each meeting of the Council. There was a demand for the question. It was put and passed by vote of the Council.

Dr. Blaisdell moved the deletion of Section 10 of Chapter IV of the by-laws as amended in 1941. This motion was seconded by Dr. Jesse C. Hales of Worcester North and passed by vote of the Council.

Dr. Blaisdell presented Section 3 of Chapter VII. This section reads as follows:

*Section 3. The Committee on Public Relations shall consist of the President as chairman and one councilor from each district society, elected as provided in Chapter III, Section 5.*

*It shall concern itself with the relations between fellows of the Society and the public.*

Dr. Blaisdell moved its adoption. The motion was seconded by Dr. Frank H. Washburn, Worcester. It was adopted by vote of the Council without debate.

Dr. Blaisdell presented Chapter VII, Section 4. It reads as follows:

*Section 4. The Committee on Legislation shall consist of one fellow from each district society, elected as provided in Chapter III, Section 5.*

*It shall study, initiate and support measures to improve standards of medicine and promote the public welfare. It shall study and oppose such measures as it may deem contrary to the public welfare.*

*It may employ counsel, subject to approval of the President.*

*District legislative committees shall be auxiliary to and under the direction of this committee.*

Dr. Blaisdell moved the adoption of this section. The motion was seconded by Dr. Royal P. Watkins, Worcester.

Dr. Channing Frothingham, Suffolk, asked if the committee under this section had the power to set a precedent for the Society without referring the matter to the Council. He subsequently supplemented the question by asking as to whether or not under the section this committee would be permitted to go down to the State House and commit the Society.

Dr. Blaisdell answered that this committee will possess no other powers than those possessed by any other committee. He added, in substance,

that there might be times when this committee would be called on to act when a special meeting of the Council might not be feasible.

Dr. Ernest L. Hunt, Worcester, suggested that the Committee on Legislation might be stronger if the President of the Society were to designate the chairman or act as chairman himself.

Dr. Charles C. Lund, Suffolk, thought that a committee of eighteen scattered all over the State might be cumbersome. He added, however, that the committee could provide for its own executive committee. He added that the members of Middlesex South, Norfolk and Suffolk live within ten miles of the State House. He referred specifically to the line which reads, "It may employ counsel, subject to approval of the President" and said he did not understand its purpose.

Dr. Ober put the question and it was carried by vote of the Council.

Dr. Blaisdell moved the deletion of Section 6 of Chapter VII of the by-laws as amended in 1941. The motion was seconded by Dr. Curley and passed by vote of the Council.

Dr. Blaisdell presented Chapter VII, Section 5, which reads as follows:

*Section 5. The Committee on Nominations shall consist of one councilor, with another as alternate, from each district society, as provided in Chapter III, Section 5.*

*It shall nominate the officers and orator of the Society, and shall cause its report to be published in the notice of the annual meeting of the Council.*

He moved its adoption. This motion was seconded by Dr. John B. Hall, Norfolk. This motion was passed by the Council without debate.

Dr. Blaisdell presented Chapter VII, Section 6, which reads as follows:

#### STANDING COMMITTEES

*Section 6. The Committee on Arrangements shall consist of five fellows.*

*It shall be responsible for all arrangements for the annual meeting of the Society.*

*The chairman shall furnish the Secretary, on or before April 15, with all the data necessary for the annual program.*

*The secretary of this committee shall record its proceedings in a volume which shall be filed with the Secretary.*

Dr. Blaisdell moved the adoption of Chapter VII, Section 6. The motion was seconded by Dr. Richard M. Smith, Suffolk, and carried by vote of the Council.

Dr. Blaisdell moved the deletion of Chapter VII, Section 1, of the by-laws as amended in 1941. This motion was seconded by Dr. Allen H. Wright, Franklin, and carried by vote of the Council.

Dr. Blaisdell presented Chapter VII, Section 7, which reads as follows:

*Section 7.* The Committee on Publications shall consist of five fellows.

It shall supervise the publications of the Society.

It shall publish, when ordered by the Council, a directory of the officers and fellows.

It shall appoint the Shattuck Lecturer in accordance with the provisions of the Shattuck bequest.

It shall inform all readers of papers and discussers of the following rules:

All papers presented at the meetings of the Society shall be the property of the Society. No paper presented in the section meetings at the annual meeting shall occupy more than thirty minutes in its delivery. Each discussion shall be limited to five minutes, unless lengthened by vote of the meeting.

All papers shall be ready for publication, typewritten and accompanied by suitable material for illustrations, if any, when read to the sections or to the Society; and as soon as read they shall be handed to the secretary of the section or of the Society for transmission to the editor of the official journal.

Discussers shall correct and promptly return to the editor for publication, if deemed proper by this committee, the stenographer's transcribed notes of their remarks.

Dr. Blaisdell moved the adoption of this section. The motion was seconded by Dr. Richard M. Smith, Suffolk.

Dr. Fallon made a suggestion which he said emanated from Dr. Walter P. Bowers to the effect that the Committee on Publications would be a better body to select the annual orator than the Committee on Nominations.

Chapter VII, Section 7, was adopted by vote of the Council.

Dr. Blaisdell moved the deletion of Chapter VII, Section 2, of the by-laws as amended in 1941. The motion was seconded by Dr. I. R. Jankelson, Norfolk, and carried by vote of the Council.

Dr. Blaisdell presented Chapter VII, Section 8, which reads as follows:

*Section 8.* The Committee on Membership shall consist of five fellows.

It shall consider applicants applying for fellowship according to the provisions of Chapter V, Section 2c.

It shall consider matters relating to honorary or associate fellowship, retirement, resignation, remission of dues, deprivation of fellowship for any cause, reinstatement following deprivation of fellowship for arrears, transfer of fellows from one district society to another, as provided for in Chapter III, Section 3, and shall make recommendations to the Council or the Executive Committee, as provided in Chapter I, Sections 10 and 11.

This committee shall confer with the representatives of the supervising censors as provided in Chapter V, Section 1.

Dr. Blaisdell moved the adoption of Section 8. The motion was seconded by Dr. James P. O'Hare, Suffolk.

Dr. Eoline C. Dubois, Hampden, voiced a criticism of the section. Dr. Blaisdell answered and said that this criticism would be answered as the Council proceeded to consider other sections of the by-laws.

Section 8 was adopted by vote of the Council.

Dr. Blaisdell moved that Chapter VII, Section 3, of the by-laws as amended in 1941 be deleted. The motion was seconded by Dr. Charles J. Kickham, Norfolk, and adopted by vote of the Council.

Dr. Blaisdell presented Chapter VII, Section 9, which reads as follows:

*Section 9.* The Committee on Ethics and Discipline shall consist of five fellows.

It shall investigate and consider, either on charges submitted in writing or on its own initiative, any alleged or apparent offense on the part of any fellow, as provided in Chapter I, Section 9.

It shall either admonish him, request his resignation or report its findings to the President with its recommendations, if as a result of its investigations and after a hearing that has been requested by the fellow, the committee finds that he is guilty of such offense.

The President acting on such recommendations shall (a) censure the fellow, or (b) refer the matter to a board of trial, as provided in Chapter VIII, Section 1.

A member of the committee shall act as prosecuting officer in cases that come before a board of trial.

There was much discussion as to the implications involved in this section, Dr. Ralph R. Stratton, Middlesex East, Dr. Fallon, Dr. Kenneth L. MacLachlan, Middlesex East, Dr. Blaisdell, Dr. Cheever, Dr. Phippen, Dr. Charles J. Kickham, Dr. Rice, Dr. Smith, Dr. Lewis S. Pilcher, Middlesex South, Dr. Bearer, Dr. Shields Warren, Suffolk, and Dr. Maurice Fremont-Smith, Suffolk, participating.

Dr. Ober instructed Dr. Fallon, Dr. Rice, Dr. A. R. Gardner, Middlesex North, and Dr. Stratton to retire and bring in a new section which would relieve the difficulties that had been raised.

Dr. Blaisdell moved that action on Section 9 be postponed, pending the return of the above-mentioned group. The motion was seconded by Dr. Fallon and carried by vote of the Council.

Dr. Blaisdell presented Chapter VII, Section 10, which reads as follows:

*Section 10.* The Committee on Medical Education shall consist of five fellows.

It shall consider matters relating to medical education.

It shall annually revise, subject to approval by the Council, the list of recognized medical schools and colleges.

Dr. Blaisdell moved the adoption of Section 10.

Dr. Halbert G. Stetson, Franklin, asked as to whether or not the word "all" following the word "consider" would add strength to the section.

Dr. Leroy E. Parkins, Suffolk, asked as to whether or not it was proposed by this section that the Committee on Medical Education take

the place of the special Committee on Postgraduate Instruction. Dr. Ober answered, "No."

Dr. Stetson offered his suggestion as an amendment. This amendment was seconded by Dr. Fremont-Smith. The amendment did not prevail.

The original motion was adopted by vote of the Council.

Dr. Blaisdell moved the deletion of Chapter VII, Section 5, of the by-laws as amended in 1941. The motion was seconded by Dr. J. L. Chereskin, Hampden, and passed by vote of the Council.

Dr. Blaisdell presented Chapter VII, Section 11, which reads as follows:

*Section 11:* The Committee on Public Health shall consist of five fellows.

It shall foster the knowledge of the prevention and treatment of disease by any appropriate measures.

Dr. Blaisdell moved the adoption of this section. The motion was seconded by Dr. Hall. It was so ordered by vote of the Council without debate.

Dr. Blaisdell moved the deletion of Chapter VII, Section 7, of the by-laws as amended in 1941. The motion was seconded by Dr. Cheever and it was so ordered by vote of the Council without debate.

Dr. Blaisdell presented Chapter VII, Section 12, which reads as follows:

*Section 12.* The Committee on Medical Defense shall consist of five fellows.

It may appoint as auxiliary members one fellow in each district.

It shall act, under the provisions of the Medical Defense Act, on applications of resident fellows for legal services in the defense of suits for alleged malpractice.

It may take counsel with both plaintiff and defendant in threatened suits.

It shall report to the Committee on Ethics and Discipline any instance coming to its knowledge wherein a fellow, in connection with a suit for malpractice, has violated the code of ethics of the Society.

Dr. Blaisdell moved its adoption. The motion was seconded by Dr. Jankelson. Dr. MacLachlan asked if the words "It may appoint as auxiliary members one fellow in each district" were part of the by-laws of 1941. Dr. Ober answered in the affirmative.

Section 12 of Chapter VII was adopted by vote of the Council.

Dr. Blaisdell moved the deletion of Chapter VII, Section 8, of the by-laws as amended in 1941. The motion was seconded by Dr. Phippen and it was so ordered by vote of the Council.

At this point the committee appointed by Dr. Ober to shape up Chapter VII, Section 9, offered the following amendment to this section as written in the text: Insert after the words "a hear-

ing" the following: "of which the fellow has been duly notified."

Dr. Blaisdell moved the adoption of Chapter VII, Section 9, as amended. The motion was seconded and it was so ordered by vote of the Council.

Dr. Blaisdell moved the deletion of Section 4, of Chapter VII, of the by-laws as amended in 1941. The motion was seconded by Dr. Cheever and it was so ordered by vote of the Council.

Dr. Blaisdell presented Chapter VII, Section 13, which reads as follows:

*Section 13.* The Committee on Society Headquarters shall consist of five fellows.

It shall supervise the maintenance of the Society Headquarters.

It shall acquire funds for expansion, subject to approval by the Council.

Dr. Blaisdell moved the adoption of this section. The motion was seconded by Dr. Cheever and it was so ordered by vote of the Council.

Dr. Blaisdell moved the deletion of Section 9, Chapter VII, of the by-laws as amended in 1941. The motion was seconded by Dr. Curley and it was so ordered by vote of the Council.

Dr. Blaisdell presented Chapter VII, Section 14, which reads as follows:

*Section 14.* The Committee on Finance shall consist of five fellows.

It shall recommend to the Council, at the February meeting, the budget for the current fiscal year.

The budget shall show in detail the proposed expenditures and their allocation to the various officers, employees, committees, or any other person or persons authorized to expend the same, and shall make available to any fellow on request the purpose of any proposed expenditure of \$100 or more. The budget shall include for purposes of comparison similar items of expenditure for the previous year, if any.

It shall consider requests for extraordinary appropriations and shall refer them, with recommendations, to the Council for action.

It shall, at the close of the fiscal year after consultation with the Treasurer and with the approval of the Council, determine the amount to be refunded to the several district societies from the unexpended balance on December 31. This amount shall be apportioned among the district societies according to the number of annual assessments paid to the Treasurer before March 1.

Dr. Blaisdell moved the adoption of this section. The motion was seconded by Dr. Fallon. This section was adopted by vote of the Council without debate.

Dr. Blaisdell moved the deletion of Section 10 of Chapter VII of the by-laws as amended in 1941. The motion was seconded by Dr. Cheever and it was so ordered by vote of the Council.

Dr. Blaisdell presented Chapter VII, Section 15, which reads as follows:

*Section 15.* The Committee on Hospital Relations shall consist of five fellows.

It may appoint as auxiliary members one fellow in each district.

It shall concern itself with the relations between the fellows of the Society and hospitals.

Dr. Blaisdell called the Council's attention to the fact that this was a new section both in language and principle. He pointed out that there were more than 5500 members of the Massachusetts Medical Society, most of whom had very definite relationships with hospitals, and that there was now no machinery in the Society endowed with authority to confer on matters pertaining to these relationships. He emphasized that this was not a witch-hunting committee. He added that the program of medical-care costs insurance upon which we are about to embark was bound to bring up problems which could be handled amiably by such a committee. He pointed out that many physicians will during the next two years be forced to give up staff positions as they enter the armed forces of our Country. He added, "What is to become of these men when they return to civilian practice? Here again is a fruitful field in which such a committee might serve a very useful purpose."

Dr. Blaisdell moved the adoption of this section. This motion was seconded by Dr. Jankelson.

Dr. Donald Munro, Suffolk, registered his opposition to the adoption of this section. He said that such a committee sooner or later would be called upon to decide whether Dr. A in Community B is to be admitted to a closed hospital staff. He added in substance that he was sure that it would be wrong for the Massachusetts Medical Society to authorize any action which would allow for the destruction of the worth-while objectives which had been built up in the care of the sick by the closed hospital staff.

Dr. Cheever thought the relationship herein involved might very well be handled by the Committee on Public Relations.

Dr. Blaisdell agreed that the Committee on Public Relations might handle this problem. He believed, however, that it would be done better by a standing committee. He believed that this proposed committee was no more likely to get into trouble than was any other committee.

Dr. Hornor said that this was the specific article in the text as offered to which he objected. He, too, thought that the business here concerned might very well be handled by the Committee on Public Relations.

Dr. Carl Bearse said that the Medical Society of the State of New York had such a committee as

is herein proposed. He quoted the secretary of this society as saying that he thought offhand that it is the most natural thing in the world that medical societies should create committees of this kind.

Dr. Elmer S. Bagnall, Essex North, expressed himself as favoring a Committee on Hospital Relations. He spoke of the former practice of the Committee on Public Relations whereby there was created, within the committee, subcommittees which considered specific problems having to do with public relations. He said that this method of organizing the committee's work had been given up in favor of the appointment of special committees by the Council which would, on a public-relations matter, report its findings to the Council through the Committee on Public Relations.

Dr. Robert N. Nye, Suffolk, asked what had been the stand of the Executive Committee as to this section when it conducted its review of these proposed by-laws.

Dr. Blaisdell answered that the Committee was in opposition.

Dr. Nathaniel W. Faxon, Suffolk, said that he favored the creation of such a committee provided it would function along the lines as suggested by Dr. Blaisdell. He believed that the Committee on Public Relations might successfully continue to function in hospital problems. He added, however, that a committee which concerned itself very definitely with hospital problems might function better.

Dr. Felton thought that this section was loaded with political dynamite.

Dr. Lewis S. Pilcher, Middlesex South, could not understand how the creation of this committee would affect the status of hospitals with closed staffs.

Dr. Bagnall pointed out that a committee of this sort would report to the Council and not embark on any wild venture on its own initiative.

Dr. William E. Browne, Suffolk, asked Dr. Blaisdell as to whether or not the committee was to have certain definite and outlined duties.

Dr. Blaisdell answered, "No; the duties would be broad." He said this committee might even deal with the question of whether the "steak shall be rare or well done." He did not, however, anticipate it would do any such thing. He believed that such a committee would be governed by at least a modicum of common sense.

Dr. Fallon expressed the opinion that the creation of this committee might very well turn out to be one of the most important things the Society has ever done. He added that he believed that we could trust the President to appoint fellows to this committee who would use their powers reasonably.

Dr William B Breed, Suffolk, was fearful of delegating to such a committee broad and far-reaching powers. He thought that the activities of this committee should be limited.

Dr Phippen recalled that during his term as President, he had appointed a committee of this general character. He asked why this committee could not take on the duties of the proposed new committee. The Secretary confirmed the existence of the committee referred to by Dr Phippen and said it was known as the Committee Appointed to Confer with the Massachusetts Hospital Association. He added that this committee had not been very active.

Dr Lund had the same view as did Dr Breed. Dr David L. Halbersleben, Norfolk, spoke in favor of the section and complimented the Committee on By Laws for its foresight.

Dr William J. Walton, Norfolk, also spoke in favor of the section.

Dr Ober called for a vote by ballot. Dr Blaisdell moved that the Council recess until 7:00 p.m. This motion was seconded and on a vote the Council recessed at 12:00 p.m.

The Council reconvened at 2:00 p.m. Dr Ober called for the result of the ballot.

The Secretary announced that 79 fellows voted for the retention of this section and 84 against.

Dr Ober announced that Section 15 of Chapter VII of the text had not been adopted.

Dr Michichin moved that the matter of hospital relations be referred to the Committee on Public Relations. The motion was seconded by Dr Beare and adopted by vote of the Council.

Dr Edward P. Bagg, vice president of the Massachusetts Medical Society, assumed the chair.

Dr Ober moved that Chapter VII of the text be amended by adding the following as Section 15.

*Section 15.* The Committee on Industrial Health shall consist of seven fellows.

It shall concern itself with medical and surgical problems in industry.

It shall consult with an advisory committee made up of representatives of agencies and others concerned with industrial health, appointed by the President.

The motion was seconded by Dr Henderson and it was so ordered by vote of the Council.

Dr Ober resumed the chair.

Dr Blaisdell presented Chapter I, Section 1, the text of which reads as follows:

#### CHAPTER I FELLOWSHIP

*Section 1.* Applicants for fellowship in the Massachusetts Medical Society are required to satisfy the censors that they are not less than twenty-one years of age, that they are of sound mind and of good character, that they have a Baccalaureate or Doctorate of Medicine from a medical school approved by the

Council or have received the approval of the Committee on Membership, that they have received a license to practice medicine within the United States, or its territories, that they do not practice medicine in a manner contrary to the code of ethics of the Society, that they have made application according to the provisions of Chapter V, and that they have paid the examination fee of three dollars.

They shall appear personally before the censors and satisfy them that the above requirements are fulfilled.

Dr Blaisdell moved the adoption of this section. The motion was seconded by Dr Munro.

Dr Frothingham inquired whether or not a professor in a medical school, who was not licensed, would be eligible for membership under this section. Dr Ober answered by saying that there is another by-law which will deal with this matter.

This section was adopted by vote of the Council.

Dr Blaisdell moved the deletion of Section 1 of Chapter I of the by-laws as amended in 1941. This motion was seconded by Dr Smith and it was so ordered by vote of the Council.

Dr Blaisdell presented Chapter I, Section 2, of the text which reads as follows:

*Section 2.* Applicants found to be so qualified shall on paying the assessment for the current fiscal year (except as hereafter provided in Section 6 of this chapter) and subscribing to the by-laws and code of ethics all within two weeks from the date of their examinations, be approved by the censors.

They furthermore shall on confirmation by the president and by the secretary of the Society, be admitted fellows of the Society and shall receive certificates of fellowship in testimony thereof signed by the President and by the Secretary.

Dr Blaisdell moved its adoption. The motion was seconded by Dr William M. Collins, Middlesex North, and it was so ordered by vote of the Council.

Dr Blaisdell moved the deletion of Section 2 of Chapter I of the by-laws as amended in 1941. The motion was seconded by Dr Curley and it was so ordered by vote of the Council.

Dr Blaisdell presented Section 3 of Chapter I of the text which reads as follows:

*Section 3.* Fellows having a legal residence in Massachusetts shall be known as resident fellows; all others as nonresident fellows.

Nonresident fellows shall receive the official publications of the Society and may attend Society meetings but may not vote, hold office or receive protection under the medical defense act of the Society.

Dr Blaisdell moved the adoption of this section. The motion was seconded by Dr Bagg and it was so ordered by vote of the Council.

Dr Blaisdell moved the deletion of Section 3 of Chapter I of the by-laws as amended in 1941. Dr Chereskin seconded the motion and it was so ordered by vote of the Council.

Dr. Blaisdell presented Chapter I, Section 4, which reads as follows:

*Section 4.* 'Honorary fellowship may be conferred on distinguished members of the medical profession.

Associate fellowship may be conferred on eminent workers in the allied sciences.

Such fellowships may be conferred by a two-thirds vote of the Council at a stated meeting, provided written nominations therefor have been submitted by two or more fellows at a previous stated meeting and have been approved by the Committee on Membership.

Honorary and associate fellows may attend and address meetings of the Society, but shall not be accorded other rights or privileges, or be subject to assessment.

Dr. Blaisdell moved the adoption of this section. Dr. Fallon seconded the motion and it was so ordered by vote of the Council.

Dr. Blaisdell moved that Section 4, Chapter I, of the by-laws as amended in 1941 be deleted. The motion was seconded by Dr. Fallon and it was so ordered by vote of the Council.

Dr. Blaisdell presented Section 5 of Chapter I, which reads as follows:

*Section 5.* Fellows who are sixty-five years of age or older whose assessments have been paid or remitted may, by vote of the Executive Committee, acting on recommendation of the Committee on Membership, become retired fellows.

They shall be in good standing, and may attend and address meetings of the Society, but shall not be accorded other rights or privileges, except that, on request annually, they shall receive the publications of the Society.

They shall not be subject to assessment.

Applications for retirement shall be addressed to the Executive Committee and sent to the Treasurer.

Retired fellows may, on their own request, be restored to active fellowship by the Executive Committee.

Dr. Blaisdell moved the adoption of this section calling the attention of the Council to the effect that the last three lines had previously been deleted by unanimous consent. The motion was seconded by Dr. Fallon.

Dr. Cheever thought it too bad that the retired members should be required to ask annually that the *Journal* be sent to them. Dr. Bearse explained that retired members frequently change their residence without notifying the Secretary of the change. The *Journal* continues to go to the old address and nobody receives it. Dr. Cheever expressed his content at this explanation.

The motion was adopted by vote of the Council.

Dr. Blaisdell moved the deletion of Section 5 of Chapter I of the by-laws as amended in 1941. The motion was seconded by Dr. Fallon and it was so ordered by vote of the Council.

Dr. Blaisdell presented Section 6 of Chapter I which reads as follows:

*Section 6.* Fellows shall be assessed such sums as are voted by the Council, and such additional sums as are voted by the district societies for their own use.

The fiscal year shall begin on the first day of January. Assessments shall be paid in advance. The first assessment paid by a fellow admitted to the Society following the December examinations shall cover his dues for the succeeding fiscal year and shall be the amount fixed for that year.

Assessments may be remitted by the Executive Committee on recommendation by the Committee on Membership.

Whenever a fellow owing more than one annual assessment pays in part, the payment or payments so made shall be considered as on the assessment or assessments longest due and for no others.

Dr. Blaisdell announced that Dr. Harold R. Kurth, Essex North, would lead the discussion on this section.

Dr. Kurth explained that by this section it was proposed to make the payment of district society assessments one of the conditions of membership in the Massachusetts Medical Society. He added that under the old by-laws, district societies had no law under which they could compel individual members to meet assessments voted by them and that this section would correct this situation.

Dr. Blaisdell moved the adoption of the section. The motion was seconded by Dr. Fallon and it was so ordered by vote of the Council.

Dr. Blaisdell moved the deletion of Section 6 of Chapter I of the by-laws as amended in 1941. The motion was seconded and it was so ordered by vote of the Council.

Dr. Blaisdell presented Section 7 of Chapter I which reads as follows:

*Section 7.* Resignations shall be submitted in writing to the Treasurer, who shall deliver them to the Committee on Membership.

This committee shall submit them with recommendations to the Executive Committee for action.

Resignations shall be accepted only from fellows whose assessments have been remitted or paid in full.

Dr. Blaisdell moved the adoption of this section. The motion was seconded by Dr. Fallon and it was so ordered by vote of the Council.

Dr. Blaisdell moved the deletion of Section 7 of Chapter I of the by-laws as amended in 1941. Dr. Fallon seconded the motion and it was so ordered by vote of the Council.

Dr. Blaisdell presented Section 8 of Chapter I which reads as follows:

*Section 8.* Fellows who, despite notification by registered letter from the Treasurer, have not paid assessments for two years, or who, despite notification by registered letter from a district treasurer, have not paid the assessments of their district society for two years, shall be deprived of the privileges of fellowship by the Executive Committee, acting on a report of the Committee on Membership, unless otherwise ordered.

Dr Blaisdell moved the adoption of this section. The motion was seconded by Dr Fallon.

Dr Browne asked if it would not be well to insert after the words "registered letter" the words "personal receipt be requested." Dr Blaisdell agreed that these words could be put in but the cost would be increased.

Dr Bignall inquired if it was clear what the words "unless otherwise ordered," meant. Dr Blaisdell said that by the use of these words, reference is made to the machinery by means of which dues are remitted.

Dr Chereskin asked how this would affect men who had gone to war. Dr Blaisdell answered that this contingency had been cared for by the Council a year ago.

Dr Blaisdell's motion to adopt this section was carried by vote of the Council.

He moved to delete Section 8 of Chapter I of the by laws as amended in 1941. Dr Fallon seconded the motion and it was so ordered by vote of the Council.

Dr Blaisdell presented Section 9 of Chapter I which reads as follows:

*Section 9* Fellows who have been convicted in a court of law of a crime involving moral turpitude or who have been guilty of attempts to harm the Society or to injure its usefulness of advertising nostrums for sale or otherwise offering them to the public or professing to cure disease by secret methods of gross violations of these by laws, of the code of ethics of the Society or of the American Medical Association of presenting false certificates or false statements of character or of educational requirements, of accepting rebates on prescriptions or appliances, or of any other conduct unbecoming a physician, may be expelled from the Society or otherwise disciplined as provided in Chapter VIII, Section 9.

A fellow who has been deprived of his license to practice medicine in the Commonwealth shall automatically cease to be a fellow of the Society.

Dr Munro called attention to the fact that earlier in the meeting the Council had given unanimous consent to change line 15 of this section so as to read Chapter VII, Section 9, and Chapter VIII, Section 1. Dr Blaisdell moved the adoption of Section 9 of Chapter I. The motion was seconded by Dr Fallon.

Dr James P. O'Hare, Suffolk, asked what was meant by the words "to injure its usefulness." Dr Fallon thought these words might be stricken out. Dr Ober asked Dr Fallon and Dr Rice to collaborate on an amendment looking toward this end.

Dr Blaisdell, in the meantime, presented Chapter I, Section 10, which reads as follows:

*Section 10* Former fellows who desire to be readmitted following retirement resignation not requested by the Committee on Ethics and Discipline, or deprivation of fellowship for arrears shall make appli-

cation in writing addressed to the Executive Committee and sent to the Secretary.

Such applications shall be referred for investigation to the board of membership of the district society concerned, which shall report with recommendations to the Committee on Membership.

This committee shall report with recommendations to the Executive Committee.

The Executive Committee may readmit former fellows so recommended.

Dr Blaisdell moved the adoption of Section 10 of Chapter I. The motion was seconded by Dr Bearse and adopted by vote of the Council.

Dr Blaisdell moved the deletion of Section 10 of Chapter I of the by laws as amended in 1941. This motion was seconded by Dr Bearse and it was so ordered by vote of the Council.

Dr Frothingham said that he still did not see how a man who was not licensed to practice medicine could become a member of the Massachusetts Medical Society.

Dr Blaisdell answered that a man who was an M.D. but without a license to practice could become an honorary member. He added that it is the feeling that the Society should be made up of fellows who are practicing medicine.

Dr Blaisdell presented Chapter II in its entirety. This chapter reads as follows:

## CHAPTER II

### MEETINGS OF THE SOCIETY

*Section 1* The annual meeting of the Society shall be held in Boston on the second Wednesday of June, unless otherwise ordered by the Council.

The order of business shall be: (1) reading of the record of the last annual meeting; (2) report by the Secretary of changes in membership during the year; (3) report by the President on the state of the Society; (4) such other business as may lawfully come before the meeting; (5) annual oration.

*Section 2* Special meetings of the Society may be called by the President or by vote of the Council, and shall be called on written request by ten councilors or one hundred fellows.

*Section 3* The deliberations of the Society shall be governed by parliamentary usage as interpreted by *Roberts' Rules of Order*, when not in conflict with the by laws of the Society.

One hundred fellows shall constitute a quorum.

Dr Blaisdell moved the adoption of Chapter II. The motion was seconded by Dr Bearse and it was so ordered by vote of the Council.

Dr Blaisdell moved the deletion of Chapter II of the by laws as amended in 1941. The motion was seconded by Dr Bigg and it was so ordered by vote of the Council.

Dr Blaisdell presented Sections 1, 2, 3 and 4 of Chapter III which he said might very well be considered together. These sections read as follows:

## CHAPTER III

## DISTRICT SOCIETIES

*Section 1.* The boundaries of district societies may be changed, and new districts may be established, by the Council.

*Section 2.* The membership of each district society shall consist only of such fellows, whether active or retired, as have legal residences within the boundaries of the district, except in cases decided otherwise by vote of the Executive Committee.

*Section 3.* Any fellow wishing to transfer membership from one district society to another without a change of legal residence must so petition the Committee on Membership in writing, stating his reasons therefor.

The Committee on Membership shall report, after consultation with the officers of the two districts concerned, its recommendations to the Executive Committee for action.

*Section 4.* Each district society may adopt by-laws and regulations for the government of its own affairs and levy assessments, provided such by-laws and regulations are not in conflict with those of the Society.

Dr. Blaisdell moved the adoption of these sections of Chapter III. The motion was seconded by Dr. Kurth and it was so ordered by vote of the Council.

Dr. Blaisdell moved the deletion of Sections 1, 2, 3 and 4 of Chapter III of the by-laws as amended in 1941. The motion was seconded by Dr. Fallon and it was so ordered by vote of the Council.

Dr. Fallon, at this point, presented an amended Section 9 of Chapter I which reads as follows:

*Section 9.* Fellows who have been convicted in a court of law of a felony involving moral turpitude, or of a crime, or who have been guilty of attempts to harm the Society; of advertising nostrums for sale or otherwise offering them to the public, or professing to cure disease by secret methods; of gross violations of these by-laws, of the code of ethics of the Society or of the American Medical Association; of presenting false certificates or false statements of character or of educational requirements; of accepting rebates on prescriptions or appliances; or of any other conduct unbecoming a physician, may be expelled from the Society or otherwise disciplined as provided in Chapter VII, Section 9 and Chapter VIII, Section 1.

A fellow who has been deprived of his license to practice medicine in the Commonwealth shall automatically cease to be a fellow of the Society.

Dr. Fallon moved the adoption of the amendment to Section 9 of Chapter I. Dr. Collins seconded the motion and it was so ordered by vote of the Council.

Dr. Blaisdell moved the adoption of Section 9 of Chapter I as amended. Dr. Fallon seconded the motion, and it was so ordered by vote of the Council.

Dr. Blaisdell moved the deletion of Section 9 of Chapter I of the by-laws as amended in 1941. The

motion was seconded by Dr. Fallon and it was so ordered by vote of the Council.

Dr. Blaisdell presented Section 5, of Chapter III which reads as follows:

*Section 5.* Each district society shall hold its annual meeting between the fifteenth day of April and the fifteenth day of May.

Each district society at this meeting shall elect by ballot from its active fellows: a president, who shall be *ex officio*, a vice-president of the Society; a vice-president; a secretary; a treasurer; councilors as below specified; four censors; a supervising censor; a commissioner of trial; a member of the Committee on Public Relations; a member of the Committee on Legislation; a member and alternate member of the Committee on Nominations.

Councilors shall be elected in number equal to one for every twenty active and retired fellows and a majority fraction thereof, as of the first day of January preceding.

Only councilors shall be eligible as supervising censors and members of the Committee on Public Relations and the Committee on Legislation.

Only councilors who have held this office for at least one year shall be eligible as members of and alternates to the Committee on Nominations. Members of and alternates to the Committee on Nominations shall not serve for more than five consecutive years and shall not be eligible for re-election for three years thereafter.

Only fellows who have been members of the Society for at least ten years shall be eligible as censors or supervising censors. The term of the supervising censors shall be five years. They shall not immediately succeed themselves. All supervising censors shall have been censors previously.

Councilors, censors, supervising censors, members of the Committee on Public Relations, members of the Committee on Legislation, members of the Committee on Nominations, and commissioners of trial shall take office at the close of the next annual meeting of the Society.

The councilors of each district society shall meet on call by the secretary at or as soon as possible after the annual meeting of the district society and elect two of their number to serve as member and alternate of the Executive Committee, in accordance with Chapter VII, Section 2.

Members of and alternates to the Executive Committee shall serve for three years and shall not be eligible for re-election for three years thereafter.

The terms of office of the alternate shall be concurrent with the term for which the member was elected.

Vacancies that occur during the term of office of such member or alternate shall be filled promptly, by vote of the councilors of the district concerned, *ad interim*.

Dr. Kurth led the discussion on this section. He called the Council's attention to the fact that this section contained many changes. He said that the committee recognized that members of the Nominating Committee should have some experience in the work of the Council. He added that the committee felt that a fellow could be a member of the Nominating Committee too long. Hence the restriction on the number of consecutive years that

any councilor could serve. He pointed to the change as it concerned the term of office of a supervising censor and added that it was important that a supervising censor retain this office over a period of years so as to become thoroughly conversant with this highly important work. He said that the final change of importance provided that the officers of the Society take office at the close of the next annual meeting of the Society instead of the day preceding this meeting.

Dr Kurth moved the adoption of Section 5 of Chapter III. Dr Beirse seconded the motion.

Dr George C. Tully, Worcester, called the Council's attention to an inconsistency which appears in line 2 of Section 4 of the text when compared with the present section under consideration. He said that, in line 2 of Section 4, the word "councilor" should be substituted for the word "fellow." Dr Blaisdell indicated that the point was well taken.

Dr Munro believed that the words "shall not immediately succeed themselves," should be deleted, since, otherwise, all the supervisors elected this year would go out of office at the same time. He moved that lines 30 and 31, beginning with the word, "They," and ending with the word "themselves," be deleted. Dr Fallon seconded this motion, which was adopted by vote of the Council.

Dr Macchichlan moved that lines 33 to 38 of Section 5 be deleted. Dr Rice seconded the motion, and it was so ordered by vote of the Council.

Dr Kurth moved the adoption of Section 5 of Chapter III as amended. Dr Fallon seconded the motion. There were several questions from councilors anent this section, all of which had for their purpose the clarification of thought with regard to it. The motion was adopted by vote of the Council.

Dr Blaisdell moved the deletion of Sections 5 and 6 of Chapter III of the by laws as amended in 1941. Dr Fallon seconded the motion, and it was adopted by vote of the Council.

Dr Blaisdell presented Section 6 of Chapter III, which reads as follows:

*Section 6.* The secretary of each district society promptly after its annual meeting shall report on appropriate forms, to the Secretary the names and residences of fellows elected, as provided in Chapter III, Section 5.

He shall promptly notify the Secretary, on the required form, of deaths of fellows in his district.

He shall also perform such duties as are defined in Chapter V.

He shall call, at or as soon as possible after the annual meeting of the district society, and before the annual meeting of the Society, meetings of the district councilors to elect the member and alternate of the Executive Committee, and shall send to the Secretary the names of the member and alternate chosen.

He shall see that a new member or alternate is chosen in a similar manner to fill a vacancy as it occurs, as provided in Section 5.

Dr Macchichlan and Dr Fallon were directed by Dr Ober to retire and confer on this section.

Dr Blaisdell presented Section 7 of Chapter III, which reads as follows:

*Section 7.* The treasurer of each district society shall collect the assessments of his district.

He shall furnish a list of fellows two years in arrears to the Committee on Membership for action as provided in Chapter I, Section 8.

Dr Kurth, in leading the discussion, said that, under the by laws as amended in 1941, the district treasurer receives fifty cents for any dues that he collects and that the money goes to him personally. He added that the committee believes that, in this day when finances are important and when there will be a loss of revenue to the Society because of the remission of the dues of those entering the Service, it would be better that this money, which amounts to about \$750, go into the treasury of the Society. He added that unquestionably part of the \$750 would be returned in dividends to the district societies. Dr Kurth moved the adoption of Section 7 of Chapter III. Dr Jankelson seconded the motion.

Dr George L. Steele, Hampden, thought that, if it was the intent not to pay the district treasurer the 5 per cent, it should be so stated in the motion.

Dr Alexander A. Levi, Middlesex South, asked that action on this section be postponed until after the discussion on Chapter V, Section 3, giving as his reason a desire to offer an amendment which might affect the section under discussion. The question was demanded from several sources. The motion was put by the President and adopted by vote of the Council.

Dr Blaisdell moved the deletion of Section 8 of Chapter III of the by laws as amended in 1941. The motion was seconded by Dr Washburn and adopted by vote of the Council.

Dr Blaisdell presented Sections 1 and 2 of Chapter IV which read as follows:

## CHAPTER IV

### THE COUNCIL

*Section 1.* The Council shall consist of councilors chosen by the district societies, the president, ex president, president elect, vice president, vice presidents *ex officio*, secretary, treasurer, and assistant treasurer of the Society, the secretaries of the district societies and the chairmen of all standing committees.

The Council each year shall hold three stated meetings in Boston unless otherwise ordered by the Council. The annual meeting shall be held on the day next preceding the annual meeting of the Society. A stated meeting shall be held on the first Wednesday in October, and another, on the first Wednesday in February.

Special meetings may be called by the President, by vote of the Council, or by the written request of ten councilors.

*Section 2.* The deliberations of the Council shall be governed by parliamentary usage as contained in *Roberts' Rules of Order*, when not in conflict with the by-laws of the Society.

Fifty councilors shall constitute a quorum.

Dr. Blaisdell moved the adoption of Sections 1 and 2 of Chapter IV. Dr. Fallon seconded the motion.

Dr. Day thought that the district secretaries and the district treasurer, both, should be *ex-officio* members of the Council.

The motion was adopted by vote of the Council.

Dr. Blaisdell moved the deletion of Sections 1 and 2 of Chapter IV of the by-laws as amended in 1941. Dr. Fallon seconded the motion, and it was so ordered by vote of the Council.

Dr. Fallon now made reference to Chapter III, Section 6, on which he and Dr. MacLachlan had previously been directed to confer.

Dr. Fallon offered the following amendments to Section 6 of Chapter III: in line 13 the word "councilors" shall read "councilors-elect." The reference in line 19, should be "as provided in Chapter III, Section 5." Dr. Bearse seconded the first of these amendments and Dr. O'Hare the second. These were both adopted on vote by the Council.

Dr. Blaisdell moved the adoption of Section 6 of Chapter III as amended. This motion was seconded by Dr. Fallon, and it was so ordered by vote of the Council.

Dr. Blaisdell moved the deletion of Section 7 of Chapter III of the by-laws as amended in 1941. Dr. Fallon seconded the motion, and it was so ordered by vote of the Council.

Dr. Blaisdell presented Section 3 of Chapter IV of the text, which reads as follows:

*Section 3.* The Council at its annual meeting, on nomination by the Committee on Nominations or from the floor, shall elect by ballot officers of the Society as follows: president-elect, who shall serve as president-elect until the second annual meeting of the Society after his election and shall, unless otherwise voted by the Council, become president on his installation in the course of that meeting, serving thereafter as president until the installation of his successor; a vice-president, secretary, treasurer, and assistant treasurer, all of whom shall assume the duties of office at the close of the annual meeting of the Society and shall hold office until their successors have been duly elected. Councilors only shall be eligible to the offices above-named.

The Council, in event of the death or the incapacity of the President-Elect, shall elect a president by ballot, at its next annual meeting, on nomination by the Committee on Nominations or from the floor.

The Council, at its annual meeting, on nomination by the Committee on Nominations or from the floor,

shall elect by ballot a fellow to deliver an oration at the annual meeting of the Society the following year.

The Council at its annual meeting shall elect, on nomination by the President-Elect or from the floor, standing committees to serve for one year from the close of the annual meeting as follows: on Arrangements; on Publications; on Membership; on Ethics and Discipline; on Medical Education; on Public Health; on Medical Defense; on Society Headquarters; on Finance; and on Hospital Relations.

Dr. Blaisdell pointed out that this section included several new ideas: namely, that the President-Elect shall take office at the second annual meeting of the Society after his election (this is to correct a bad situation in the by-laws as amended in 1941); that a provision is made for an assistant treasurer, which will be considered under a separate article; that the words "unless otherwise ordered by the Council" protect the Society in the event that the President-Elect is found unworthy to succeed as president; that, in the case of the death or the incapacity of the President-Elect, a provision was made for the continuity of the office of president; and that the President-Elect shall nominate committees which will serve during his term of office.

Dr. Bearse moved as an amendment that the words "Hospital Relations" in lines 33 and 34 be deleted and the words "Industrial Health" be substituted. The amendment was seconded by Dr. Smith, and it was so ordered by vote of the Council.

Dr. Blaisdell moved the adoption of Section 3 of Chapter IV as amended. This motion was seconded by Dr. Fallon.

Dr. Nye raised the point that this section should either make reference to Chapter VI, Section 1, as this latter concerns the nomination of committees by the President in case of the death of the President-Elect, or that the section under discussion should itself provide for this contingency.

Dr. Nye, Dr. Fallon and Dr. Bearse were directed by Dr. Ober to confer on this section. They did so and Dr. Fallon offered the following amendment to Section 3 of Chapter IV: insert after the word "floor" the phrase "or as provided in Chapter VI, Section 1." Dr. Munro seconded the amendment, and it was so ordered by vote of the Council.

Dr. Blaisdell's motion for the adoption of Section 3 of Chapter IV as amended was seconded by Dr. Fallon, and it was so ordered by vote of the Council.

Dr. Blaisdell moved the deletion of Section 3 of Chapter IV of the by-laws as amended in 1941. The motion was seconded by Dr. Fallon, and it was so ordered by vote of the Council.

Dr. Blaisdell presented Sections 4, 5, 6 and 7 of Chapter IV, which read as follows:

*Section 4* The Council shall elect at the stated meeting in October, on nomination by the President or from the floor, the Auditing Committee, composed of two fellows who are not councilors

This committee, following the close of the fiscal year, shall require by a certified public accountant an examination of the assets and securities of the Society in the custody of the Treasurer, and of the Treasurer's books and accounts

This committee shall verify the accountant's examination and report its findings at the stated meeting of the Council in February

*Section 5* The Council may at any meeting fill vacancies in office or elect committees

*Section 6* The Council may vote to establish or abolish sections for the consideration of scientific papers at the annual meetings of the Society, and shall appoint the first chairman and secretary of a new section so established

Each section shall elect annually a chairman and a secretary to serve for one year from the close of the annual meeting at which they are elected

The duties of these officers shall be to arrange the programs of the meetings of their sections under the rules of the Council

The chairman shall preside at the meetings of the section at the following annual meeting, the secretary shall take charge of the papers presented and shall transmit them promptly to the editor of the official journal of the Society

*Section 7* The Council shall, on nomination by the President or from the floor, elect delegates to the House of Delegates of the American Medical Association in accordance with the by laws of that association

It may, on nomination by the President or from the floor, elect delegates to such other medical meetings as it deems suitable

Dr Blaisdell moved the adoption of Sections 4, 5, 6 and 7 of Chapter IV. The motion was seconded by Dr Kurth, and it was so ordered by vote of the Council

Dr Blaisdell moved the deletion of Sections 4, 5, 6 and 7 of Chapter IV of the by laws as amended in 1941. The motion was seconded by Dr Brain and F Conley, Middlesex South, and it was so ordered by vote of the Council

Dr Blaisdell presented Section 8 of Chapter IV, which reads as follows

*Section 8* The Council shall vote the salaries of its officers and employees, the appropriations for its officers and committees, and such other appropriations as it deems suitable

No officer or committee shall exceed the voted appropriation

No salary to any officer or employee and no regular appropriation shall be increased except on recommendation of the Committee on Finance and by vote of the Council

The Treasurer is authorized, on recommendation of the Committee on Finance to pay such monies as may be necessary in the event of emergency, the expense of which shall be determined by the President

Dr Blaisdell moved the adoption of Section 8 of Chapter IV. The motion was seconded by Dr

Conley. It was so ordered by vote of the Council

Dr Blaisdell moved the deletion of Sections 8 and 9 of Chapter IV of the by laws as amended in 1941. The motion was seconded by Dr Fallon and it was so ordered by vote of the Council

Dr Blaisdell presented Section 1 of Chapter V which reads as follows

## CHAPTER V

### CENSORS AND SUPERVISING CENSORS

*Section 1* The supervising censors shall constitute a Board which shall meet annually on the day appointed for the annual meeting of the Council. This board shall elect a chairman and also three of their members to sit with the Committee on Membership. Five supervising censors shall constitute a quorum

The secretary of the Society shall act as secretary of the Board. He shall call special meetings at the request of the chairman or five supervising censors. He shall keep a permanent record of the proceedings of the Board and shall provide materials necessary for conducting examinations of applicants for fellowship

The Board at its annual meeting shall adopt a uniform plan for the examination of applicants

The supervising censors, on request, shall be paid traveling expenses

The supervising censors shall be chairmen of their respective boards of censors and shall cause the examinations of applicants to be conducted in strict conformity to the plan adopted by the Board of Supervising Censors

The censors of the several district societies shall meet for the examination of applicants semiannually on the first Thursday in May and on the first Thursday in December

The approval of at least three censors shall be necessary to qualify an applicant

An applicant failing two examinations may not again apply until three years have elapsed from the date of the last application

Dr Fallon led the discussion on this section and moved its adoption. The motion was seconded by Dr Munro, and it was so ordered by vote of the Council

Dr Fallon moved the deletion of Section 1 of Chapter V of the by laws as amended in 1941. The motion was seconded by Dr Bearse and it was so ordered by vote of the Council

Dr Fallon presented Section 2 (a) of Chapter V which reads as follows

*Section 2 (a)* The secretary of a district society may receive not later than February 15 for the censors' examination in May or later than September 15 for the examination in December an application for fellowship submitted on the proper form by an applicant whose legal residence is within the district of that society

The secretary of the Suffolk District Society may receive and officials of that society may act on an application for nonresident fellowship

The secretary of the district society shall verify each applicant's diploma and deliver his application to the Secretary not later than February 20 or September 20, respectively

The official journal shall publish, in the first number on or after March 5 or October 5, a list of all applicants. This list shall include name, address, medical school and date of graduation of the applicant; name and address of the secretary of the district society concerned; and if a sponsor is required, the name and address of the sponsor.

Fellows are requested to send to the secretary of the district society concerned, *not later than*, respectively, March 20 or October 20, *confidential* written opinions on the qualifications of applicants.

Dr. Fallon announced that there was a misprint in the third line—the word “or” should be changed to “nor.” He moved the adoption of Section 2 (a) of Chapter V. The motion was seconded by Dr. Bearse, and it was so ordered by vote of the Council.

Dr. Fallon moved the deletion of Section 2 (a) of Chapter V of the by-laws as amended in 1941. The motion was seconded by Dr. Bearse, and it was so ordered by vote of the Council.

Dr. Fallon presented Section 2 (b) of Chapter V, which reads as follows:

(b) The secretary of a district society shall receive an application from a graduate of a discontinued medical school, a foreign medical school or any medical school not approved by the Council only when:

The applicant has possessed a license to practice medicine in the United States or its territories for at least five years;

The applicant has submitted with his application the name and address of a sponsor who is a fellow of the district society concerned; and

The sponsor has caused to be delivered by fellows of the Society to the secretary of the district society *confidential* written opinions on the qualifications of the applicant.

He pointed out that the committee felt that an applicant for membership in the Massachusetts Medical Society should have practiced for five years in the United States before being eligible for membership. He said that there were some members who felt that such an applicant should have practiced for five years in Massachusetts before being so eligible. The committee did not share this latter view because it felt that our means of intercommunication was such that we could obtain sufficient information about a prospective candidate no matter in what state or states he had practiced.

Dr. Fallon moved the adoption of Section 2 (b) of Chapter V. This motion was seconded by Dr. Bearse.

Dr. Alexander A. Levi, Middlesex South, moved as an amendment that in line 32 after the word “years” the following be inserted: “This license shall be verified by the district secretary and the data relating to it shall be recorded in the applicant’s application blank.” Dr. Bearse seconded

the amendment, and it was so ordered by vote of the Council.

Dr. Munro said that, in connection with the five-year law, he had taken the liberty of writing to the supervising censors and that 85 per cent of them believed that residence in Massachusetts for five years should be one of the requirements of eligibility. He, therefore, moved that the phrase in line 31 of Section 2 (b) of Chapter V, reading “in the United States or its territories” be deleted and that the phrase “in the Commonwealth of Massachusetts” be substituted. The motion was seconded by Dr. Hornor.

Dr. Robert T. Monroe, Norfolk, in opposing the amendment spoke as follows:

The Committee on Medical Education has objected strenuously and seriously on every occasion to the five-year rule directed against the graduates of foreign medical schools, always on the ground that injustice is done in particular instances if this rule is applied to all. When this job was taken out of its hands and put in the hands of the Committee on Membership, at our last meeting there seemed to be some feeling that the Society is being flooded with fellows from foreign medical schools. That has not been shown in the one year that I have been on the committee, and I can give figures from the last examination on April 4 of this year. Twenty-three graduates of foreign medical schools were considered by the committee, and of these 12 were rejected and 11 were accepted; of the 11 accepted, 6 were born in the United States and took their medical work abroad, 2 are not citizens, 1 has been in this country for a little over five years and has a good job and 2 are professors of medicine rather lately come to this country—one who came to take a professorship in Harvard last fall and the other, an Australian, who has a professorship at Tufts Medical School. From those figures there is no evidence that we are being flooded by graduates of foreign medical schools in this Society.

I object not only strenuously to leaving in the term “in the United States or its territories,” but I object still more strenuously to limiting it to Massachusetts.

Dr. Munro’s amendment was put to a vote by the President and lost, the vote being 26 for and 34 against.

Dr. Monroe moved to amend Section 2 (b) of Chapter V by striking out the words “in the United States and its territories.” This motion was seconded by Dr. Lund.

Dr. Fallon believed that the text should, in respect to Section 2 (b) of Chapter V, remain as it is. He pointed out that we should not only be concerned with an applicant’s scientific attainments but that there should likewise be available to us some knowledge as to how he comports himself. He added that such knowledge can only be had when the applicant resides amongst us for a reasonable time or when there is readily available to us information on this point from those among

whom the applicant has resided for such reasonable time.

Dr. Curley favored the retention of the text as it stands.

Dr. Lund advocated the adoption of Dr. Munroe's amendment.

Dr. Munro said that he felt that the reasons advanced against this five-year restriction were not valid.

There was a demand for the question from several sources.

Dr. Ober put the question, and the amendment was lost. Dr. Fallon withdrew his original motion, and Dr. Bearse withdrew his second.

Dr. Fallon moved the adoption of Section 2 (b) as amended. The motion was seconded by Dr. Bearse, and it was so ordered by vote of the Council.

Dr. Fallon moved the deletion of Section 2 (b) of Chapter V of the by-laws as amended in 1941. The motion was seconded by Dr. Bearse and it was so ordered by vote of the Council.

Dr. Fallon presented Section 2 (c) of Chapter V which reads as follows:

(c) The censors may admit to examination an applicant who is a graduate of a discontinued, foreign or unapproved medical school only when such applicant has been considered by the board of membership concerned and approved by the Committee on Membership.

The board of membership of a district society shall consist of the president, secretary and supervising censor.

It shall gather such information as it deems advisable to determine whether an applicant is conscientious, capable and reputable. It shall interview personally such applicant. It shall either approve or disapprove him for examination by the censors.

The secretary of the district society shall deliver to the chairman of the Committee on Membership, *not later than*, respectively, April 1 or November 1, all pertinent correspondence and other data together with the record of such applicant's approval or disapproval, with reasons therefor, by the board of membership.

The Committee on Membership shall have custody of such documents so long as needed and then shall deliver them to the custody of the Secretary; they shall remain *confidential*.

The Committee on Membership shall consider the application of each applicant approved for censors' examination by a board of membership. It shall determine finally whether or not such applicant may take that examination.

The Committee on Membership shall not consider the application of any applicant disapproved by a board of membership except on the written request of a majority of that board of membership.

Decisions on applications by the Committee on Membership shall be final, and shall remain in force for two years.

The Committee on Membership shall notify the secretary of the district society concerned and each applicant considered of its decision *not later than*, respectively, April 20 or November 20.

Dr. Fallon pointed out that there were two changes to be noted in this section. The Committee on Membership, rather than the Committee on Medical Education, will take care of all matters pertaining to membership. The local committees on membership, under the setup in vogue at present, have only advisory powers. Under this section as now presented, both the local committee and the central committee have the right to turn down an applicant. He added that there might be times when it would be embarrassing for the local committee to turn down a candidate who, in the opinion of that committee, should be turned down. The decision in such cases can be left to the central committee, and the decision of that committee will be final.

He pointed out that this section contained a further provision to the effect that a candidate once refused admission cannot reapply until two years have elapsed.

Dr. Fallon moved the adoption of Section 2 (c) of Chapter V. The motion was seconded by Dr. Bearse.

Dr. Norman A. Welch, Norfolk, offered the following amendment to Section 2 (c) of Chapter V: insert in line 6 after the word "Membership" the following: "In the case of the rejection of a candidate by the Committee on Membership when said candidate has already been approved by the district committee, this candidate shall have the right of appeal through his district committee to the Executive Committee of the Council. At this hearing the candidate shall be represented by a councilor of his district and the Committee on Membership shall be represented by one of its members." The amendment was seconded by Dr. Bearse.

Dr. Welch supported this amendment by a forceful argument.

Dr. Blaisdell said that the procedure outlined in the amendment would prolong the workings of the committees involved.

Dr. Welch did not agree with the previous speaker. He thought that when somebody is willing to fight it out in favor of a candidate, he should have the right to go to the Executive Committee.

Dr. Henderson expressed his approval of the text as it relates to this section.

Dr. Fallon said that much time had been given to this section. He added that he thought that the by-laws committee had, in it, effected a working compromise between two extremes.

There was a demand for the question. It was put and lost.

The question then came on the adoption of Section 2 (c) of Chapter V, and it was so ordered by vote of the Council.

Dr. Fallon presented Sections 3 and 4 of Chapter V, which read as follows:

*Section 3.* The secretary of each district society shall be the secretary of the district board of censors.

He shall furnish applicants with forms adopted by the Board of Supervising Censors.

He shall keep a record of all applicants for fellowship, and see that each applicant pays the examination fee of three dollars, that this fee is sent *promptly* to the Treasurer, that each successful applicant subscribes to the by-laws and code of ethics and within two weeks pays the assessments for the current year.

He shall furnish each new fellow with a copy of the *Digest, By-laws, Code of Ethics, and Medical Defense Act* of the Society.

He shall present, on the proper form and promptly after each examination, a bill to the Treasurer for censors' services, together with a list of all applicants examined.

The secretary of each district society shall fill out, sign and deliver promptly to the Secretary certificates stating that the successful applicants have complied with the requirements of the by-laws.

*Section 4.* The censors and secretaries shall be paid from the funds of the Society three dollars for each applicant examined. The amount paid shall be divided equally among those officers attending and taking part in the examinations.

Dr. Fallon moved the adoption of Sections 3 and 4 of Chapter V. Dr. Curley seconded the motion.

Dr. Levi offered the following amendment: after the word "ethics" in line 9, insert a period, delete from line 10 the words "and within two weeks pays the assessments for the current year," and add the following sentence: "He shall promptly send the names of successful applicants to the district treasurer, informing him that the assessments must be paid within two weeks, and upon information from the district treasurer, he shall notify the Secretary that all requirements have been fulfilled." He moved the adoption of the amendment. Dr. Bearse seconded the motion.

Dr. Levi spoke, out of his experience as a district secretary, acquired over a period of ten years, in support of the amendment.

Dr. Tully thought that this amendment would complicate the procedure.

The motion was put and lost.

Dr. Stratton offered the following amendment: insert in line 13 of Section 3 of Chapter V, after the words "*Code of Ethics*" the words "of the Society and of the American Medical Association."

Dr. Maclachlan suggested that Dr. Stratton include in his amendment the insertion in line 9, Section 3 of Chapter V, after the word "ethics," the words "of the Society and of the American Medical Association." Dr. Stratton accepted this suggestion; whereupon Dr. Maclachlan seconded the amendment and it was so ordered by vote of the Council.

Dr. Fallon moved the adoption of Section 3 of Chapter V as amended. Dr. Bearse seconded the motion.

Dr. Rice at this point wanted to know why the censors were paid. Dr. Blaisdell answered that it was an old custom.

Dr. Collins asked how much time the censors put in. Dr. Munro answered approximately three hours each year.

Dr. Ober announced that the question before the Council was the adoption of Section 3 of Chapter V as amended. It was so ordered by vote of the Council.

Dr. Fallon moved the deletion of Section 3 of Chapter V of the by-laws as amended in 1941. Dr. Bearse seconded the motion, and it was so ordered by vote of the Council.

Dr. Rice moved that Section 4 of Chapter V of the text be deleted. The motion was seconded by Dr. Collins, and it was so ordered by vote of the Council.

Dr. Bearse presented Chapter VI, Section 1, which reads as follows:

## CHAPTER VI

### OFFICERS

*Section 1.* The President shall preside at the meeting of the Society, of the Council, of the Executive Committee and of the Committee on Public Relations.

He may call a meeting of any committee of the Society.

He shall approve all valid bills against the Society after they have been suitably endorsed by the officer, delegate, or chairman or majority of the committee that has incurred the indebtedness specified in the bill as provided in Chapter VII, Section 1.

He shall sign the certificates of all delegates, at the diplomas of all new fellows if he is satisfied that they have met the requirements of Chapter I.

He shall nominate to the Council all members, committees, all delegates to other medical societies, all fellows to fill vacancies among the officers, censors, censors and commissioners of trial of the Society unless otherwise provided by the by-laws or by order of the Council.

He shall make appointments to fill vacancies *ad interim* in any of the offices of the Society.

He shall be a member *ex officio* of all committees.

He shall, in accordance with specific recommendations by the Committee on Ethics and Discipline, either admonish fellows or appoint a board of trial, as provided in Chapter VIII, Section 1.

He shall report on the state of the Society at the annual meeting.

He shall call one meeting of the Executive Committee between meetings of the Council, and others at his pleasure.

In the event of the death or incapacity of the President-Elect, the President, at the annual meeting of the Council, shall nominate members of standing and special committees, unless otherwise provided in the by-laws.

Dr. Bearse moved the adoption of Section 1 of Chapter VI. The motion was seconded by Dr. H. C. Petterson, Norfolk.

Dr Halbersleben offered the following amendment after line 20, insert the following "He shall nominate no more than one member from one district for any committee" This amendment was seconded by Dr John P. Treanor, Jr, Norfolk. Dr Halbersleben in speaking for the amendment said that it was inspired by a desire to see committee duties spread over the entire state as a means of fostering interest in the Society.

Dr Blaisdell said that, while he was entirely in sympathy with the motives behind the amendment, he was opposed to its inclusion in the by laws. Dr Hornor was likewise opposed.

Dr Halbersleben withdrew his amendment with the consent of the seconder. He offered a new amendment which was just the same as his first with the exception that where the first amendment spoke of one member, the one now offered spoke of two members. This latter amendment was seconded by Dr John C. V. Fisher, Norfolk, and on vote by the Council it was lost.

The question now came on the adoption of Section 1 of Chapter VI. This motion prevailed by vote of the Council.

Dr Bearse moved the deletion of Section 1 of Chapter VI of the by laws as amended in 1941. This motion was seconded by Dr Munro, and it was so ordered by vote of the Council.

Dr Bearse presented Chapter VI, Section 2, which reads as follows:

*Section 2. In the absence of the President the Vice President shall perform the duties of the President and in the absence of both, the senior ex officio Vice President in point of membership in attendance shall perform the duties of the President.*

Dr Bearse moved the adoption of Section 2 of Chapter VI. The motion was seconded by Dr Curley, and it was so ordered by vote of the Council.

Dr Bearse moved the deletion of Section 2 of Chapter VI of the by laws as amended in 1941. Dr Conley seconded the motion, and it was so ordered by vote of the Council.

Dr Bearse presented Section 3 of Chapter VI which reads as follows:

*Section 3. The President Elect shall assist the President in the performance of his duties in such manner as the President may direct and in so doing shall be considered to represent the President.*

At the annual meeting of the Council following the annual meeting at which he was elected, he shall nominate members of standing and special committees unless otherwise provided for in the by laws.

He shall be a member ex officio of all committees.

Dr Bearse moved the adoption of Section 3 of Chapter VI. Dr Conley seconded the motion, and it was so ordered by vote of the Council.

Dr Bearse moved the deletion of Section 3 of Chapter VI of the by laws as amended in 1941. Dr

Chereshkin seconded the motion, and it was so ordered by vote of the Council.

Dr Bearse presented Chapter VI, Section 4, which reads as follows:

*Section 4. The Secretary shall attend all meetings of the Society, the Council and the Executive Committee, and shall record their respective proceedings in separate volumes.*

He shall cause to be engrossed and shall sign the diplomas of new fellows if satisfied that they have met the requirements of Chapter I, and shall issue all diplomas and certificates of fellowship.

He shall notify fellows of votes by the Council or Executive Committee granting permission to retire, to resign, to transfer district membership or to have dues remitted and of votes depriving them of or reinstating them in the privileges of fellowship.

He shall be ex officio secretary of all boards of trial, the Board of Supervising Censors, the Committee on Publications and the Committee on Ethics and Discipline, and shall keep the records of each in separate volumes.

He shall have custody of the seal of the Society and of all books, papers, manuscripts, prints and paintings belonging to the Society except such as are in charge of the Treasurer.

He shall issue notices of the meetings of the Council. He shall issue to every fellow one month before the annual meeting of the Society a program, listing the time and place of that meeting and of the stated meetings of the Council, the boards of censors for that year, and information concerning the payment of assessments and the distribution of publications if there are any proposed amendments to the by laws. He shall provide that each program is accompanied by a copy thereof.

He shall transfer fellows from one district to another under the terms of Chapter III, Section 3, and shall report to the Society at its annual meeting the changes in membership during the year.

He shall conduct official correspondence and shall notify officers, delegates and members of committees of their appointments and of their duties.

He shall keep a directory of the fellows and shall publish the same under the direction of the Committee on Publications at such intervals as may be determined by the Council. He shall furnish this on request to fellows not in arrears.

He shall have jurisdiction over the work of the Executive Secretary.

He shall perform such other duties as the Society or the Council may require.

Dr Bearse moved the adoption of Section 4 of Chapter VI. Dr Fillon seconded it, and it was so ordered by vote of the Council.

Dr Bearse moved the deletion of Section 4 of Chapter VI of the by laws as amended in 1941. Dr Blaisdell seconded the motion, and it was so ordered by vote of the Council.

Dr Bearse presented Chapter VI, Section 5, which reads as follows:

*Section 5. The Treasurer shall collect and care for all monies due the Society and shall have custody of the treasury records. All monies received by any committee, officer or employee on behalf of the Society shall be paid forthwith to the Treasurer.*

He shall be bonded in such sum and manner as may be directed by the Council, on recommendation of the Committee on Finance.

He shall, under the direction of the Council, sue for claims due the Society and shall sell, rent or lease any estate belonging to the Society.

He shall pay only such bills as have been countersigned by the proper officer or delegate, or the chairman or majority of the committee incurring the indebtedness, as provided in Chapter VII, Section 1, and have been approved by the President.

He shall render to the Council at its February meeting a full written report of the assets and liabilities on December 31 of the previous year, and also of the financial transactions of the Society during that year.

He shall attend the meetings of the Committee on Finance, furnish the committee with such data as it may require and shall make all investments and re-investments of the Society's funds, with authority to buy or sell securities subject to the approval of this committee.

He shall arrange for the Cotting luncheons.

He shall familiarize the Assistant Treasurer with the fiscal concerns of the Society.

He shall perform such other duties as the Society or the Council may require.

Dr. Bearse moved the adoption of Section 5 of Chapter VI. The motion was seconded by Dr. Chereskin, and it was so ordered by vote of the Council.

Dr. Bearse moved the deletion of Section 5 of Chapter VI of the by-laws as amended in 1941. Dr. Blaisdell seconded the motion, and it was so ordered by vote of the Council.

Dr. Bearse presented Chapter VI, Section 6, which reads as follows:

*Section 6.* The Assistant Treasurer shall assist the Treasurer in the performance of such duties as the Treasurer may direct.

In the event of the death or the incapacity of the Treasurer, the Assistant Treasurer shall assume the duties of the Treasurer until cessation of the incapacity or the next annual meeting of the Council.

He shall be bonded in such sum and manner as may be directed by the Council, on recommendation of the Committee on Finance.

Dr. Bearse moved the adoption of Section 6 of Chapter VI. Dr. Conley seconded the motion.

Dr. Hornor moved as an amendment that the word "until" be inserted after the word "or" in line 7. This amendment was seconded by Dr. Conley, and it was so ordered by vote of the Council.

Dr. Bearse withdrew his original motion with the consent of the seconder. He moved the adoption of Section 6 of Chapter VI as amended. Dr. Conley seconded the motion, and it was so ordered by vote of the Council.

Dr. Bearse presented Chapter VI, Section 7, which reads as follows:

*Section 7.* The Executive Secretary, under the jurisdiction of the Secretary, shall assist the officers, the

Council and such committees as may request his services.

He shall hold office at the pleasure of the Executive Committee.

Dr. Bearse moved the adoption of Section 7 of Chapter VI. Dr. Conley seconded the motion.

Dr. Rice inquired as to how the Executive Secretary is elected or appointed.

Dr. Ober answered by saying that he is elected by the Executive Committee of the Council.

Dr. Rice inquired why he should not work under the direction of that committee. "It says here," he added, "that the Secretary shall have jurisdiction over the work of the Executive Secretary." He further commented that the Executive Secretary would not know for whom he was working.

Dr. Fallon, in response, said that that was just the reason that the committee decided to do things in this way. He added that in the past the Executive Secretary did not know for whom he was working. Furthermore, the committee felt that the responsibility for his work should be centralized.

There was a demand for the question from several sources.

Dr. Ober put the motion, and it was so ordered by vote of the Council.

Dr. Bearse moved the deletion of Section 6 of Chapter VI of the by-laws as amended in 1941. Dr. Fallon seconded the motion, and it was so ordered by vote of the Council.

Dr. Bearse presented Chapter VI, Section 8, which reads as follows:

*Section 8.* The traveling and incidental expenses of the officers and committees elected by districts and of standing committees of the Society, on request, shall be paid by the Treasurer, on presentation of an itemized bill duly approved by the President.

Dr. Bearse moved the adoption of Section 8 of Chapter VI. This motion was seconded by Dr. Fallon.

Dr. Curley moved as an amendment that in line 2, after the word "committees," there be inserted the words "of the Society." Dr. Fallon seconded the amendment, and it was so ordered by vote of the Council.

Dr. Bearse, with the consent of the seconder, withdrew his original motion to adopt Section 8 of Chapter VI. He moved the adoption of Section 8 of Chapter VI as amended. Dr. Conley seconded the motion and it was so ordered by vote of the Council.

Dr. Bearse moved the deletion of Section 7 of Chapter VI of the by-laws as amended in 1941. Dr. Fallon seconded the motion, and it was so ordered by vote of the Council.

Dr Blaisdell asked the unanimous consent of the Council to reconsider the vote by which Section 4 of Chapter VII was adopted. On a vote this consent was given.

Dr Blaisdell moved that, in line 2 of Section 4 of Chapter VII, the word "fellow" be deleted and the word "councilor" substituted. Dr Fallon seconded the motion, and it was so ordered by vote of the Council.

Dr Blaisdell moved the adoption of Section 4 of Chapter VII as amended. Dr Fallon seconded the motion, and it was so ordered by vote of the Council.

Dr Fallon presented Section 1 of Chapter VIII, which reads as follows:

### CHAPTER VIII

#### BOARDS OF TRIAL

*Section 1* A board of trial shall consist of five of the commissioners of trial, appointed by the President to consider charges against a fellow recommended for trial by the Committee on Ethics and Discipline.

The President shall designate a time and place for the meeting of such board, and shall cause due notice thereof to be given to the complainants and to the accused and to all members of the district society of which the accused is a member.

A board of trial may hear fellows who appear in the interest of the accused but legal counsel shall be excluded.

Failure of the accused to appear or be represented at the trial shall be considered *prima facie* evidence of the truth of the charges, and a verdict may be rendered accordingly. In case of conviction, a board shall recommend such sentence as it shall deem best as provided in Chapter I Section 10. The Secretary shall enter on the records the proceedings of each board of trial and shall report them to the Society at the next annual meeting for final action.

The Secretary shall notify the accused of the findings of a board of trial and of the action of the Society thereon and he shall notify the several district societies of the sentence imposed.

Dr Fallon moved the adoption of Section 1 of Chapter VIII. The motion was seconded by Dr Blaisdell, and it was so ordered by vote of the Council.

Dr Fallon moved the deletion of Section 1 of Chapter VIII of the by laws as amended in 1941. Dr Rice seconded the motion, and it was so ordered by vote of the Council.

Dr Fallon presented Section 2 of Chapter VIII which reads as follows:

*Section 2* Each commissioner, and each prosecuting officer shall be paid ten dollars a day for attendance plus his incidental expenses.

It shall be a duty of any fellow summoned by the Committee on Ethics and Discipline to appear as a witness before a board of trial. No fellow shall be relieved of this duty without an excuse satisfactory to such a board.

Dr Fallon moved the adoption of Section 2 of Chapter VIII. Dr Harold G Giddings, Middlesex South, seconded the motion, and it was so ordered by vote of the Council.

Dr Fallon moved the deletion of Section 2 of Chapter VIII of the by laws as amended in 1941. Dr Bearse seconded the motion, and it was so ordered by vote of the Council.

Dr Blaisdell presented Chapter IX which reads as follows:

### CHAPTER IX

#### AMENDMENTS

These by laws may be amended by a majority vote at any annual meeting of the Society, provided the proposed amendment or amendments shall have been submitted previously in writing to the Council, shall have been approved by that body by vote and shall have been published and forwarded to each fellow, along with the program of the meeting of the Society whereat they are to be considered.

Dr Blaisdell moved the adoption of Chapter IX. Dr Bearse seconded the motion, and it was so ordered by vote of the Council.

Dr Blaisdell moved the deletion of Chapter IX of the by laws as amended in 1941. Dr Fallon seconded the motion, and it was so ordered by vote of the Council.

Dr Blaisdell moved the adoption of the report of the committee as a whole with the respective amendments thereto. Dr Hornor seconded the motion, and it was so ordered by vote of the Council.

Dr Bagnall moved that the Council extend a rising vote of thanks to the committee for this work. The motion was seconded by Dr Charles J Kichham, and it was so ordered amidst great applause.

Dr Blaisdell moved that the meeting adjourn. This motion was seconded by Dr Bearse and carried, after Dr Ober had expressed his thanks to all who had seen the session through.

Adjournment was at 5.30 p.m.

MICHAEL A TIGHE, *Secretary*

# CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTE-MORTEM AND POST-MORTEM RECORDS AS USED  
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

## CASE 28201

### PRESENTATION OF CASE

A thirty-seven-year-old French-Canadian shoe-worker was admitted to the hospital because of hoarseness, cough and dysphagia.

The patient was in good health until about thirteen months before entry, when there was insidious onset of cough. Two months later, after a bout of coughing, he suddenly became so hoarse that he was barely able to talk. Although this acute aphonia soon passed, the patient remained slightly hoarse from then on. In the eight months before entry, he had a paroxysmal cough, productive of thick greenish sputum. Five weeks before entry, there was sudden onset of dysphagia, solid foods seeming to stick in the throat at the level of the thyroid cartilage. During the period of all of these symptoms, there was also insidious appearance of slight dyspnea on exertion, loss of 12 pounds of weight and increased nervousness.

The family history was irrelevant. There was no known exposure to tuberculosis. The patient had had a mastoidectomy seven years before entry, with residual deafness in the right ear. He had urethral discharge on two occasions, twelve and seven years before entry.

On admission, the patient appeared well developed and nourished. Hearing was diminished in the right ear, and a right mastoid scar was present. The tonsils were absent. The left vocal cord lay in the midline, and was paralyzed; the right cord was normal. The trachea was deviated slightly to the right. The lungs were clear, and the heart seemed normal. The abdomen was normal.

The blood pressure was 110 systolic, 70 diastolic. The temperature was 98.6°F., the pulse 80, and the respirations 20.

Examination of the blood showed a red-cell count of 5,020,000 with 13 gm. hemoglobin, and a white-cell count of 8100 with 69 per cent polymorphonuclears. The blood Hinton reaction was negative. The sedimentation rate was 1.6 mm. per minute. The urine and stools were normal. A tuberculin test was positive, in a dilution of 1:50,000.

A roentgenogram of the chest with a barium swallow showed a mass in the upper mediastinum, just behind the sternum and above the arch of the

aorta. The esophagus was narrowed, particularly posteriorly at an area, about 4 cm. long, just above the upper edge of the aortic arch. The mucosa appeared destroyed in the area of narrowing. The lung fields were clear.

On the seventh hospital day, bronchoscopy was performed. The left vocal cord was found to be paralyzed. The carina appeared markedly thickened, reddened, irregular and fixed. In the region of the right upper-lobe bronchial orifice, there was an irregular, reddened thickened mass. The right middle and lower bronchial orifices seemed normal. There was an irregular, reddened outcropping mass in the left main bronchus, producing obstruction. Biopsies from the carina, from the right and from the left bronchi showed acute and chronic inflammation, with necrosis and granulation tissue.

Three days later, esophagoscopy was performed, showing no evidence of extrinsic pressure and no mucosal abnormality, except for a slightly granular, questionably polypoid area about 30 cm. distant from the upper incisors. This level was considered to be somewhat below that of the lesion described in the roentgenogram. Biopsy of this area showed no diagnostic abnormality.

Five days later, a small axillary lymph node was removed for biopsy. Sections showed hyperplasia.

In the next two weeks, the patient was given a total of 1200 r of x-ray to the anterior mediastinum, and 1100 r to the posterior mediastinum. Following this, a roentgenogram of the chest showed no change in the mass in the upper mediastinum. There seemed to be definite involvement of the wall of the esophagus.

The patient was discharged unimproved, and was followed in the Out Patient Department. Three weeks later, a roentgenogram of the chest again showed no change in the mediastinal mass. There was constant irregular narrowing of the esophagus in the area previously described, apparently due to an intrinsic lesion. A week later, bronchoscopy and esophagoscopy were again performed.

### DIFFERENTIAL DIAGNOSIS

DR. EDWARD D. CHURCHILL: "The left vocal cord lay in the midline, and was paralyzed." From that item of the examination, we go back to the episode in the history, eleven months previously, of a bout of coughing, hoarseness and a period of acute aphonia. Paralysis of one vocal cord need not give hoarseness and does not cause acute aphonia. Consequently, we have no right to infer that the left vocal-cord paralysis came on eleven months previously. I bring that up as an important consideration because, with vocal-cord

paralysis due to cancer, other manifestations of that cancer might well be expected in eleven months.

The sedimentation rate, although not corrected, was elevated. How many adults thirty-seven years of age, Dr. King, show a positive tuberculin reaction in a dilution of 1:50,000 without active disease?

DR. DONALD S. KING: I think plenty of them do.

DR. CHURCHILL: Then, the positive test in high dilution is not significant?

DR. KING: No; I do not believe so. I show a strong reaction in a dilution of 1:100,000 myself.

DR. CHURCHILL: But you are in daily contact with patients with positive sputum.

DR. KING: Yes; but I do not have active disease.

DR. CHURCHILL: Dr. Hampton, can you show us the mass in the upper mediastinum beneath the sternum above the arch of the aorta?

DR. AUBREY O. HAMPTON: At the arch of the aorta, there is a pressure defect behind the esophagus and sternum, pressing on the esophagus here.

DR. CHURCHILL: But quite a distance from the sternum?

DR. HAMPTON: I think it was quite intimate with the esophagus.

DR. CHURCHILL: But not a substernal mass?

DR. HAMPTON: No; not between the trachea and sternum. It is at the right margin of the esophagus and posterior; I should say that it is a prevertebral mass.

DR. CHURCHILL: That is quite a different interpretation. Certainly, there was enough evidence to go ahead with esophagoscopy and, possibly, also bronchoscopy because of the cough and sputum. The left vocal-cord paralysis was confirmed, and the carina of the trachea was thickened, reddened and fixed. In the right upper-lobe orifice, there was an irregular thickened, reddened mass, and on the left side the same thing but with an outcropping in the bronchus. The definition of outcropping is "tissue without an intact mucous-membrane covering." The endoscopist differed sharply with the radiologist because he said that the esophagus showed no evidence of extrinsic pressure and no mucosal abnormality except for a slightly granular, questionably polypoid area about 30 cm. distant from the upper incisors.

Dr. Benedict, where is 30 cm. from the upper incisors? Tell me when I reach it on this film.

DR. EDWARD B. BENEDICT: About 15 cm. above the diaphragm.

DR. CHURCHILL: Not in the region of the mass! At this point, just above the diaphragm, the questionable polypoid area was observed and a biopsy taken, but no microscopic abnormality was recognized. In other words, the endoscopist did not see any abnormality until this low level was reached

and then found something indefinite and not significant. It is obvious that a diagnosis of either lymphoma or cancer was entertained because the patient was given x-ray therapy—1200 r to the anterior mediastinum, and 1100 r to the posterior. This I assume to be in the diagnostic range rather than full therapy. Is that correct?

DR. HAMPTON: A sensitive carcinoma dose, larger than the usual lymphoma dose, was given because it was thought that the gastrointestinal tract was involved, and growths in that region require heavier dosages than the average.

DR. TRACY B. MALLORY: The X-ray Department frankly suggested that it be given as a diagnostic measure.

DR. CHURCHILL: The mass did not change. Again, the X-ray Department stated that there was definite involvement of the wall of the esophagus. Three weeks later, there was still no change in the mass, and it was therefore proved not to be a radiosensitive tumor.

Again, the roentgenologists stated very emphatically, "due to an intrinsic lesion." They became more and more emphatic as the irritation of the report of the endoscopist reached them. Then the esophagoscopist got irritated in turn, and he did both bronchoscopy and esophagoscopy. This, I take it, settled the matter.

Dr. Hampton, do you still believe just as emphatically that this represents both extrinsic deformity and intrinsic involvement of the mucosa of the esophagus?

DR. HAMPTON: The radiologist considered that the wall of the esophagus was certainly involved. Whether in the beginning the mucosa was involved, I do not know, but that is the picture of a mass in the wall of the esophagus. We may have become a little more emphatic because of this film at a later examination in which the mucosa does look definitely involved.

DR. CHURCHILL: Which side is this?

DR. HAMPTON: The left.

DR. CHURCHILL: The left recurrent nerve again!

DR. HAMPTON: Yes; there is a suggestion of prominence, but I cannot be sure of it. It may be that the mediastinal tissues are pushed over. It may be that there is no pressure on the esophagus here. I cannot be sure there is anything where the recurrent laryngeal nerve is.

DR. CHURCHILL: There are two or three things to decide. Going back to the problem of recurrent-nerve paralysis, in the absence of aneurysm, this almost invariably means cancer. I think we have seen one case of pulmonary tuberculosis with recurrent-nerve paralysis. Is that so, Dr. King?

DR. KING: I do not remember the verification of it. We have not got one that I am sure of.

ere is one where we thought the x-ray evidence s good

Dr CHURCHILL: There is no enlargement of the : auricle?

Dr HAMPTON. No.

Dr CHURCHILL: We come down, I should say, discounting the history of the period of acute monia and conclude that at some time a left urrent nerve paralysis occurred. It could have urred at any time within the previous eleven nths, but not necessarily so long ago. Did the ore than lymphoma" dosage and re-examination ee weeks later reveal any change?

Dr HAMPTON: If anything, it was worse.

Dr CHURCHILL. I shall rule out lymphoma, ich is a radiosensitive tumor.

Let us leave neoplasm and go back to the possi- ty of tuberculosis, because of this strange find- g of a mass partially obstructing the right upper e bronchus and an outcropping mass obstruct- g the left. It is very difficult to link up that iding with the chest film. No films were taken nspiration and expiration, but I doubt whether ey are needed.

Dr HAMPTON: The lungs certainly do not look ry emphysematous. In the oblique view, one n see the right main bronchus to this point, and e right upper-lobe bronchi are not seen, prob- ly because they are projected on end. The left ain bronchus is seen up to the point where the ophagus covers it. There is no mass right in that ea, which must be beyond the carina.

Dr BENEDICT: In my bronchoscopic report, I d not say complete obstruction; I said partial nstruction of the left.

Dr CHURCHILL: Could this be the endobron- al type of tuberculosis? Information about the ick greenish sputum that the patient was raising as been withheld. I do not know why he was using it from the lung unless from bronchial nitation. Certainly, with thick greenish sputum nd a bilateral endobronchial lesion, we are ent- led to know whether the sputum was positive

Dr MALLORY: The sputum was examined twice nd reported negative for tubercle bacilli

Dr CHURCHILL. Could the distortion of the ophagus have been due to a tuberculous lymph ode secondary to the bronchial lesion? I think it nlikely and rule out endobronchial tuberculosis s a likely possibility.

That brings us back to neoplasm. Certainly, I ee little evidence on which a diagnosis of primary arcinoma of the lungs can be based. Conceivably, small cancer might exist in the periphery of the ung invading the mediastinum, with lymph node nvolvevement. But a cancer that is outcropping in, he bronchus would have yielded a positive biopsy, nd also would have produced some obstruction in

at least one of the segmental bronchi of the upper lobe.

I am going to cast my lot with the X-ray De- partment, and say that until proved otherwise, this mass be considered primary cancer of the esophagus, with direct extension into the left primary bronchus and perhaps with lymph node metastases causing distortion of the carina and invasion of the left recurrent nerve

Dr KING. We had one case, Dr. Churchill, that showed tuberculosis of the wall of the esophagus. Of course, since tuberculosis would not involve the bronchus in the same way, we can discard that diagnosis.

Dr. HAMPTON. If you could believe absolutely that these first films show only a submucosal intramural lesion, what should you think?

Dr CHURCHILL. That question brings us back to the old question whether cancer of the esopha- gus can start in the deep layers and not show mucosal ulceration. We thought that some ten years ago, but now I wonder what we were seeing. In other words, I shall doubt the existence of that entity until I see it again, because our older observa- tions were not too well supported.

Are you ready to call it cancer of the esophagus by x-ray examination?

Dr HAMPTON. I should say that whatever the disease was, it was invading the esophagus, and there are not many things that will invade the esophagus. I think there is one possibility, other than cancer.

Dr MALLORY. Do you want to tell us that, Dr. Hampton?

Dr HAMPTON. I thought Dr. King was going to. It is mediastinal tuberculosis, with perforation of the esophagus

Dr MALLORY. Dr. Benedict, you might describe the final endoscopy.

Dr BENEDICT. The second bronchoscopy con- firmed the first bronchoscopy. There was exactly the same appearance, with a mass of reddened inflammatory tissue involving the carina, left main bronchus and right main bronchus in the region of the upper lobe. The esophagoscopy did show, on second examination, extrinsic pressure pushing the esophagus forward, but definitely no mucosal involvement.

Dr. HAMPTON: Not even edema?

Dr BENEDICT: No

Dr HAMPTON. Edema could explain the x-ray picture satisfactorily.

Dr LOWREY F. DAVENPORT. Does not the char- acter of the symptoms disturb you with that diagnosis?

Dr CHURCHILL. You mean cough and sputum, then the hoarseness and then the dysphagia? Yes; it points toward lung rather than esophagus

DR. MALLORY: Although we have seen just that with cancer of the esophagus.

DR. KING: Since we have raised the question of tuberculosis, have you ever seen tuberculosis of the bronchus with this story and these physical signs?

DR. DAVENPORT: No.

DR. KING: It is hard to imagine that, even if the lymph node perforated through into the bronchus. It is the first case of this sort that we have seen.

DR. HAMPTON: We have seen cancer of the breast metastasize to the mediastinum and esophagus in this way. I do not see why a tuberculous lymph node could not do the same thing. Such a case was reported in this conference, but we examined the esophagus by x-ray and found nothing. The patient died of tuberculous mediastinitis, which perforated into the esophagus.

#### CLINICAL DIAGNOSIS

Mediastinal tumor (? pulmonary or esophageal carcinoma).

#### DR. CHURCHILL'S DIAGNOSIS

Carcinoma of the esophagus, with extension to bronchus and regional lymph-node metastases.

#### ANATOMICAL DIAGNOSIS

Tuberculosis of bronchus.

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: On the final endoscopic examination, no change in the esophagus was noted. More biopsies were taken, and this time it was possible to make a positive diagnosis of tuberculosis of the bronchus. We could only guess the rest, but I should think that there was mediastinal tuberculosis, pressing on the esophagus and very probably invading the recurrent laryngeal nerve.

### CASE 28202

#### PRESENTATION OF CASE

A fifty-two-year-old lawyer was admitted to the hospital because of a "heart attack" on the preceding day.

The patient was in good health until three years before entry, when there was insidious onset of nervousness and fatigue and a sense of lifeless depression following work. At this time, there also appeared a sense of constriction in the back of the neck, which was relieved by osteopathic treatment. The patient also experienced occasional mild shooting pain in the region of the left nipple but had no substernal pain or shortness of breath. He consulted a physician, who found his heart slightly enlarged to the left with regular sounds of good quality. The aortic second sound was greater than

the pulmonic, and there were no significant murmurs. The lungs were clear and full. Physical examination was otherwise negative. The blood pressure was 184 systolic, 120 diastolic, on one examination and 162 systolic, 110 diastolic, on another. The Hinton reaction of the blood was negative, and the nonprotein nitrogen level was 30 mg. per 100 cc. The urine was normal. A roentgenogram of the chest showed that the heart was just slightly enlarged in all its diameters. The great vessels were rather dense and tortuous but showed no evidence of aneurysm. Their appearance suggested an aortitis. There was scoliosis of the dorsal spine, with convexity to the left in the lower portion and to the right in the upper portion. General relaxation was recommended by the physician. The patient remained fairly well for the following three years, complaining occasionally of fatigue. His wife stated that he had been under a nervous strain because of business worries.

On the day before entry, while fighting a brush fire with others of his family, the patient suddenly said to his wife, "I am having a heart attack; I am dying," and slumped to the ground. He was taken to his house temporarily. He was unconscious and very restless, and breathing was difficult, with long periods of apnea. According to his wife and physician, he seemed to suffer no pain. The following day, his breathing was better, and he was taken to the hospital, approximately twenty-four hours after the onset of the attack.

On admission, the patient was semistuporous, with poor color, and was breathing irregularly. Heart sounds were of poor quality but were regular. A systolic murmur was audible over the precordium, with transmission into the axilla. The radial arteries were tortuous and palpable. The extremities were warm. The nailbeds and lips were moderately cyanotic. The veins of the neck were not distended.

The blood pressure was 60 systolic, 40 diastolic. The temperature was 100.5°F., the pulse 75, and the respirations 20.

The blood Hinton reaction was negative, and the blood nonprotein nitrogen was 65 mg. per 100 cc.

An electrocardiogram showed absence of R<sub>4</sub> and unusually high T waves, with concave upstroke in Leads 2 and 3. There was moderate left-axis deviation and normal rhythm, with a rate of 120. All leads showed upright T waves.

The patient was given morphine. He continued restless and cyanotic. Although he passed no urine, his bladder did not become distended. He had not voided since the onset of the attack, but catheterization twelve hours after onset yielded

90 cc. of urine. The following morning, respiration was stertorous, with tracheal rales and intermittent periods of apnea. The blood pressure was 70 systolic, 40 diastolic, and the pulse was 100 and regular. At no time did the patient complain of pain. Death occurred twenty-two hours after admission.

### DIFFERENTIAL DIAGNOSIS

Dr. EDWARD F. BLAND: This case presents a rather unusual combination of symptoms and signs: stupor, hypotension and a relatively slow pulse. The only thing that seems reasonably certain is that there must have been a vascular accident somewhere; the question is, Was it in the central nervous system or the coronary circulation, or did it involve some other organ? The first thing that is striking is that the patient became quickly stuporous or unconscious following some sort of discomfort in the chest, and I assume from the record that he remained more or less stuporous until the time of death. Another striking feature is the blood pressure, which was low in the absence of the usual signs of peripheral shock: the patient was warm, and the pulse was not fast. The pulse does not have to be fast with peripheral circulatory collapse but it usually is, so that this combination of stupor, low blood pressure and relatively slow pulse is a bit difficult to fit together. We have a little freedom in connection with the pulse, however, because when the patient was first admitted it was said to be 75 and then later on, not long before death, it was 100. Somewhere in between, it got up to 120 by electrocardiogram.

Did this patient have a subarachnoid hemorrhage? I do not believe so. The absence of headache at the beginning, although a little unusual, does not exclude it, but it would be difficult to account for the extreme hypotension on this score. Furthermore, since we are given no information about stiffness of the neck, I think we can assume that it was not present, and there were no neurologic signs. Therefore, if we assume that this was not a subarachnoid hemorrhage, or some vascular accident in the central nervous system, we must account for the stupor on some other score. Perhaps I am overemphasizing the unconscious state. Am I, Dr. Smith?

Dr. WILLIAM D. SMITH: Just a bit.

Dr. BLAND: The next most striking feature seemed to be the extremely low blood pressure, which remained thus until death. It could be due to a number of conditions.

The abrupt onset promptly brings to mind dissecting aortic aneurysm, which, furthermore, comes on with unusual exertion. Whether the patient actually had pain in the chest seems uncertain,

but it could not have been a very striking symptom. Something, however, must have happened in the chest. At least, the patient's attention was temporarily directed, so long as he was conscious, to his chest. If this were an aortic dissection, and we know that dissecting aneurysm can do bizarre things, the first thing we find difficulty in accounting for is the hypotension. It is conceivable, and such an event has been recorded, that the dissection involved the mouths of both subclavian vessels, which might give one a false reading of hypotension in the arms, but we must still account for the stupor, which I must assume was due to the extremely low blood pressure. This, in turn, probably accounted for the failure of the kidneys to secrete urine and for the rising nonprotein nitrogen. Dissecting aneurysm could do all these things, but this would hardly be consistent with two days of life without some other suggestive evidence indicating a serious interference with the circulation to the lower extremities. Therefore, I cannot make a diagnosis of dissecting aneurysm of the aorta.

Finally, Did this patient have a relatively painless but large myocardial infarct? I am inclined to think that this is the most likely explanation, but I am not very happy with that diagnosis either. We do see now and then, of course, an extremely low blood pressure following a large myocardial infarct, and in some cases infarcts at the base of the heart are associated with a relatively slow pulse, since vascular lesions at the base of the heart are more apt to disturb also the circulation to the auricles than lesions responsible for apical infarcts. At this point, I think the electrocardiogram might be a good deal of help, and I should like to see the tracing, since I am suspicious of the high concave T waves in Leads 2 and 3 mentioned in the record, because shortly after a large myocardial infarct at the base of the heart, the waves might be large and high. After seeing the tracing shown here on the screen, I am disappointed. All this film shows is a left-axis deviation of moderate degree, a full length PR interval up to 0.19 second, upright T waves, more or less normal shape in Leads 2 and 3 and a chest lead that shows a very minute R wave, possibly absent. I had hoped for more positive help from the electrocardiogram pointing to myocardial infarction; instead, it casts a good deal of doubt on the correctness of this diagnosis. Therefore, one begins to think in terms of something more unusual and hence less likely. This low blood pressure could be due, of course, to constriction of the heart. It could be due to obstruction to the circulation inside the heart—for example, by a thrombus, which is usually formed in the presence of considerable valvular disease,

notably mitral stenosis. I have not seen it in any other situation. The other condition that might account for the low blood pressure is cardiac tamponade, but we are specifically told that the veins were not distended; therefore, this possibility is untenable.

So far as various unlikely possibilities are concerned, there occasionally has been described a syndrome with extreme hypotension and collapse in connection with bilateral hemorrhage in the adrenal glands. In the course of serious infection in childhood, hemorrhage may occur into both adrenal glands, with symptoms resembling acute Addison's disease. Dr. Grantley W. Taylor,\* some years ago, described such a case of bilateral hemorrhage into both adrenal glands following an operation. The patient went into collapse, stupor and hypotension, and died. Death was not explained until the post-mortem examination, when the bilateral apoplexy of the adrenal glands was found. I cannot fit that into this picture.

In summary, I am left with myocardial infarction, in spite of the relatively normal electrocardiogram, as my choice of the three most likely diagnoses noted above,—the other two being subarachnoid hemorrhage and dissecting aneurysm,—and I should explain the renal failure and the cloudiness of the sensorium as secondary to the critically low blood pressure.

DR. TRACY B. MALLORY: Does anyone want to champion any of the other possibilities Dr. Bland has mentioned?

DR. PAUL D. WHITE: The patient did not have characteristic electrocardiographic evidence of acute myocardial infarction. In a patient so sick, there should be more definite findings of acute coronary occlusion than absence of R<sub>4</sub> alone, which might be due to a faulty position of the electrode or to an old infarct. We should expect greater changes in the ST segment in at least one of these four leads, if he was so sick from myocardial infarction alone.

DR. BLAND: Yes; that is the most serious objection to myocardial infarction.

DR. SMITH: I came to the same diagnosis that Dr. Bland came to but less logically. There were various things that I did not consider at all. I ruled out dissecting aneurysm in the first place on the entire absence of pain, and I tried very hard to get a story of pain. We asked the patient's wife if she thought that he had had pain. She said, "No." I telephoned the local doctor, who also said that the patient had had no pain. Dissecting aneurysm without pain was something outside my experience. Another thing that influenced me against it was the low blood pressure, because generally the blood

pressure is tolerably well maintained in dissecting aneurysm. I therefore came to the same clinical diagnosis as Dr. Bland.

DR. EARLE GLENDY: When was the first blood-pressure reading made in relation to the onset?

DR. SMITH: As soon as the patient came in to the hospital, which was twenty-four hours after the onset.

DR. GLENDY: With massive dissection of the aorta, it is possible for the coils of the dissected inner portion of the aorta to occlude the aorta; then the blood pressure falls very rapidly, and the heart fails.

DR. SMITH: The patient did not impress me as having heart failure.

DR. F. DENNETTE ADAMS: Did he not have shock?

DR. SMITH: Yes; we gave oxygen and morphine.

DR. ADAMS: Then, why did he not have dissecting aneurysm? They ordinarily do not rupture in the absence of pain, but he perhaps had stupor, or relative stupor before he had an opportunity to tell about it.

DR. WHITE: I should like to emphasize that last statement of Dr. Adams. I have been caught out here several times by the absence of pain in patients with vascular shock. This patient did, however, have enough pain in the beginning to think he had a "heart attack." At least, figuratively, he put his hand to his chest; what he felt was bad enough to make him think he was going to die. Whether he had coronary thrombosis or dissecting aneurysm, I believe he had sudden and severe chest pain at the very beginning before he collapsed; the very abruptness favors somewhat dissection of the aortic wall.

#### CLINICAL DIAGNOSES

Hypertensive and coronary heart disease.  
Myocardial infarct.

#### DR. BLAND'S DIAGNOSES

Coronary thrombosis.  
Myocardial infarction.

#### ANATOMICAL DIAGNOSES

Dissecting aneurysm of aorta, with slight hemorrhage into mediastinum, pericardium and pleural cavities.  
Pulmonary edema.  
Hemorrhage into lungs.  
Hypertrophy of heart, hypertensive type.  
Subepicardial and subendocardial hemorrhage, both auricles.  
Arteriosclerosis of aorta and of coronary and pulmonary arteries, moderate.  
Acute focal myocardial infarction.

\*Taylor, G. W. Intestinal diverticulosis, pernicious anemia, bilateral suprarenal apoplexy: report of a case. *New Eng. J. Med.* 202:269-271, 1930.

## PATHOLOGICAL DISCUSSION

DR. MALLORY: At autopsy, the first thing evident was that the ascending aorta and arch were swollen and bright red. Dissecting gingerly into his area, we found a tube filled with partially clotted blood and then inside it was another tube consisting of the inner half of the aortic wall. The dissection was complete from the level of the coronary mouths down to the bifurcation of the aorta and some distance into each iliac artery; it had re-entered the right iliac but not the left. There was also dissection some distance down the superior mesenteric artery, the adrenal arteries, both subclavians, both carotids and a minute portion of the splenic.

DR. WHITE: Not in the coronaries?

DR. MALLORY: No; we could not make out any dissection in the coronaries. There was blood around the mouths of both coronaries, but in each instance it seemed to be external to the wall of the artery. About 3 cm. above the aortic cusps was an almost complete transverse tear of the aorta. A second tear was also present, running almost at right angles to the first one down to a point only 3 mm. from the mouth of the right coronary artery. There was no atheroma in the ascending portion of the aorta in the region of the tear. It began in the region of the arch and became progressively more severe as one passed down to the iliacs. From the gross examination, it looked as if the mesenteric artery had been definitely occluded by the dissection, but the intestines were not infarcted, so that if occlusion were ever complete, it could not have

been present for any significant period. The coronary arteries, in contrast, did not seem to be occluded, but sections of the myocardium showed innumerable small foci of acute necrosis throughout the entire left ventricle. There was, in effect, almost total infarction.

DR. WHITE: That would have to be two days old for one to see it?

DR. MALLORY: Yes; an extremely acute change—as yet no leukocytic reaction but a definite change in the staining of the muscle fibers, and also a slight change in the character of the nuclei of the endothelial cells in the immediate region of each focus.

DR. BLAND: Therefore, the process was there when the electrocardiogram was taken.

DR. MALLORY: Yes.

There were traces of blood-stained fluid in the pericardium and pleural cavities, evidently no more than a little oozing through the tissues, with no external rupture and no question of cardiac tamponade. The greater parts of both kidneys were normal. One area of partial infarction was found on the kidney where the tubules were infarcted, but the glomeruli appeared entirely normal. That is a condition that is sometimes seen when a critical level of oxygen deficit is met with. The kidney tubules are more sensitive to anoxemia than the glomeruli, and hence it is possible to get differential necrosis of tubules without glomerular changes. I think the anuria was due to the state of shock and diminished blood pressure.

DR. BLAND: Was the brain examined?

DR. MALLORY: No.

SUBSCRIPTION TERMS: \$6.00 per year in advance, postage paid, for the United States (medical students, \$3.50 per year); Canada, \$7.04 per year, Boston funds; \$8.52 per year for all foreign countries belonging to the Postal Union.

MATERIAL for early publication should be received not later than noon on Friday.

THE JOURNAL does not hold itself responsible for statements made by any contributor.

COMMUNICATIONS should be addressed to the *New England Journal of Medicine*, 8 Fenway, Boston, Massachusetts.

## PROCUREMENT AND ASSIGNMENT SERVICE

Every physician should read the communication from Major Sam F. Seeley, director of the Procurement and Assignment Service, which appeared in the May 2 issue of the *Journal of the American Medical Association*. Every physician should return his enrollment blank promptly. The demand for doctors in the Army is still great. At least 10,000 more will be needed by the end of the year. The Navy will also require more physicians, although its need is not so great as that of the Army.

Heretofore, there has been considerable delay in answering applications for commis-

sions in the Medical Corps of the United States Army. This delay and the resulting uncertainty have undoubtedly deterred many physicians from applying for commissions. To overcome this, the Army has adopted a new method.

Beginning about May 15, recruitment boards consisting of a medical-corps officer and a line officer will be sent into each state east of the Mississippi. These boards will work in co-operation with the state chairmen of the Procurement and Assignment Service, securing from them the names of physicians, and will then communicate with these men, initiate the applications and physical examinations, make final decisions, and administer the oath of office immediately. By this method, a physician can be assigned to duty within fourteen days of the time he applies and is examined.

For the most part, commissions will be given in the grade of first lieutenant. The great need of the Army at present is for battalion and regimental surgeons for service with troops. Applications for commissions for captain may be granted between the ages of thirty-seven and forty-five. Above that age, commissions will not be granted except in rare instances and for a special need. No commissions will be given by these boards for affiliated units.

The Navy will send a medical officer from the First Naval District to co-operate with the state chairmen of Maine, New Hampshire, Massachusetts, Vermont and Rhode Island, to perform a similar service.

Physicians will not be commissioned in either the Army or the Navy unless they are cleared as available by the Procurement and Assignment Service.

The Army and the Navy are doing their utmost to cut red tape and make it as easy as possible for physicians to receive commissions. Physicians of the First Corps Area and Naval District should set an example to the rest of the Nation by their willingness and promptness to respond to this call. The need is great; the response must be prompt.

## ALCOHOLISM: A MEDICAL AND COMMUNITY PROBLEM

Of the three greatest public-health problems in the United States,—tuberculosis, syphilis and alcoholism,—only alcoholism has not yet been completely accepted as a medical problem. It is in endemic condition, however, and its prevalence can be estimated when one recalls that only a small proportion of those who drink to excess are diagnosed and are receiving treatment.

Alcoholism is difficult to define, but it is generally agreed that a person who uses alcohol to the extent of being unable to maintain his position in a family, occupational or community group is to be considered an alcoholic; such a person presents a medical and, particularly, a psychiatric problem. The moral aspects of drinking are no longer emphasized, but because of the physical and mental damage inevitably resulting from prolonged drinking, alcoholism must be considered a public-health problem and handled with the technics of preventive medicine.

Acute and chronic alcoholism result in part from personal psychologic inadequacy. Thus, in addition to individual tolerance and habituation, personal factors determine largely why some persons can drink a given volume of alcohol in a given period and suffer no untoward effects, whereas others, under the same conditions, demonstrate abnormal behavior. These variations appear to be conditioned principally by personal experience and may be molded by the forces to which the person has been exposed as a child and as an adolescent. The difficulties encountered before the onset of alcoholism may be precipitating factors rather than actual causes.

Generalizations about the causes of acute and chronic alcoholism are inconclusive, but the person who is unwilling or unable to face the realities of life frequently becomes an alcoholic. Such a person tends to substitute for mature reactions the infantile regressive patterns that in childhood were expressed in temper tantrums, too prolonged bedwetting and other neurotic traits. One of the

commonest forms of neurotic behavior is drinking to excess.

Prolonged drinking usually results in some form of neuropsychiatric disorder that is often not recognized. It may be an avitaminosis, such as alcoholic polyneuritis or pellagra caused by faulty dietary habits. Delirium tremens may develop, or there may be a frank alcoholic psychosis, such as Korsakow's syndrome. Between 1915 and 1935, 6 per cent of the cases of alcoholism admitted to the Boston City Hospital were diagnosed as delirium tremens. About 60 per cent of all patients admitted to Massachusetts mental hospitals in the last twenty-five years gave a history of excessive drinking.

The cost of hospital care of alcoholics is large, especially since most of them are cared for without charge in institutions supported by states or cities. The maintenance of courts for the penal disposition of inebriates and the expense of maintaining alcoholic addicts in state penal institutions and the county houses of correction increase this cost. In addition the relief care of their families and dependents, whose income and earning power have been lost, necessitates large local or state appropriations every year.

There are very few places in Massachusetts where alcoholics are welcomed for treatment unless they can afford the high costs of private institutions. They are not wanted at general hospitals, for the most part, and if received at all, are cared for only during the acute phases of their condition or sent in presumably for observation or study. They are not accepted at state mental institutions unless they are suffering from alcoholic psychoses or equally severe mental illnesses in which alcoholism plays a part. Few private physicians are equipped by training to treat alcoholic patients, and private psychiatrists are reluctant to accept them, for they are usually not co-operative or are resistant to treatment. There are a few small hospitals, such as the Washingtonian Hospital in Boston, where they can receive therapy.

In the treatment of acute or chronic alcoholism, when the patient's physical condition has been

improved by rest, the administration of sedative and analgesic drugs to relieve nervous tension, the restoration of fluids, dietary readjustment and such specific measures as are appropriate, psychotherapy should be attempted. The first requisite is that the patient express a desire to overcome the habit and agree to co-operate with the therapist. Complete abstinence from alcoholic beverages is an absolute necessity. The aim of psychotherapy is to review the past history, to bring into focus the factors that have built up the drinking habit, and to help the patient to reorganize his life on the basis of total abstinence from drinking. Boredom and social inadequacy, which often play a large part in the temptation to drink, can be partially remedied with thought and planning.

In Massachusetts, facilities for treating indigent alcoholic patients are sorely needed, and should be made available through clinics and in general hospitals. Clinics operated with the aim of preventing secondary neurologic and psychiatric complications should be established in connection with the institutions at present administered by the Department of Mental Health. These clinics cannot be established without a concurrent educational program, in which federal, state and local authorities should participate. This program might be similar to the one that has been so effective in directing attention to syphilis as a public-health problem. The clergy, the press and progressive physicians can be very effective in promoting co-operation between alcoholic patients and the organizations that can aid them.

## IN MEMORIAM

### NORMAN PAUL HERSAM

1884—1942

Norman Paul Hersam was born in Stoneham fifty-seven years ago. He graduated from the Stoneham High School, the University of California and Harvard Medical School. He interned at the Providence City Hospital and took post-graduate work in plastic surgery at the Massachusetts General Hospital. He then practiced medicine in his own town until his death, living on the street named after his grandfather.

Dr. Hersam was school physician in Stoneham for over twenty years, and at the time of his death he was a censor in the Middlesex East District Medical Society. He was a fellow of the American Medical Association and was on the staffs of the Choate Memorial Hospital in Woburn and the Winchester Hospital.

Dr. Hersam had many hobbies. He loved fine music and had the skill of a concert pianist. He was an artist of great talent, and his home is adorned by many of his paintings. His skill as a woodcraft was widely known; he carved many objects and made many violins that were noted for their beautiful tones. To know Dr. Hersam intimately was to cherish a friendship everlasting.

BE IT RESOLVED: That the members of the Middlesex East District Medical Society by his death on January 15, 1942, have lost a beloved and respected associate and one who at all times carried the highest standard of ethics and clean living; and

BE IT FURTHER RESOLVED: That a copy of these resolutions be spread upon the records of the society and that the secretary be directed to send a copy to his wife, Mrs. Maybelle Jane Hersam and to the *New England Journal of Medicine*.

JOSEPH H. KERRIGAN, M.I.  
RICHARD W. SHEEHY, M.I.

## MEDICAL EPONYM

### PAGET'S DISEASE (OSTEITIS DEFORMANS)

Sir James Paget (1814-1899), Bart., D.C.L., LL.D., F.R.S., consulting surgeon to St. Bartholomew's Hospital, read a paper "On a Form of Chronic Inflammation of Bones (Osteitis Deformans)" in 1876 before the Royal Medical and Chirurgical Society of London. It appears in the *Medico-Chirurgical Transactions* (42:37-63, London, 1877). A portion of the text follows:

The disease affects most frequently the long bones of the lower extremities and the skull, and is usually symmetrical. The bones enlarge and soften, and those bearing weight yield and become unnaturally curved and misshapen. The spine, whether by yielding to the weight of the overgrown skull, or by change in its own structures, may sink and seem to shorten with greatly increased dorsal and lumbar curves; the pelvis may become wide; the necks of the femora may become nearly horizontal, but the limbs, however misshapen, remain strong and fit to support the trunk.

In its earlier periods, and sometimes through all its course, the disease is attended with pains in the affected bones, pains widely various in severity and variously described as *rheumatic*, *gouty*, or *neuralgic*, not especially nocturnal or periodical. It is not attended

with fever. No characteristic conditions of urine or faeces have been found in it. It is not associated with syphilis or any other known constitutional disease, unless it be cancer.

In three out of the five well-marked cases that I have seen or read of cancer appeared late in life; a remarkable proportion, possibly not more than might have occurred in accidental coincidences, yet suggesting careful inquiry.

R. W. B.

## MASSACHUSETTS MEDICAL SOCIETY

### OFFICE OF THE SECRETARY

The following letter, which should be of interest to all members of the Massachusetts Medical Society, was recently received from J. W. Holloway, Jr., director of the Bureau of Legal Medicine and Legislation of the American Medical Association.

MICHAEL A. TIGHE, *Secretary*

\* \* \*

TO THE SECRETARIES OF THE STATE MEDICAL ASSOCIATIONS:—  
The Senate Committee on Military Affairs has reported H. R. 4476 to the Senate with the recommendation that it pass.

The first section of the bill, as reported, reads, in part.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That the Secretary of War be, and hereby is, authorized out of any moneys available for the War Department . . . to provide for the employment of interns who are graduates of or have successfully completed at least four years' professional training in reputable schools of medicine or osteopathy in the Medical Department, at not to exceed \$720 per annum.

This authorization will represent permanent legislation. It does not make it mandatory that the War Department select interns from osteopathic schools and if the present high standards are maintained in the Medical Department, no such appointments will be made. The authorization, however, does constitute to a certain extent a Congressional viewpoint that osteopaths will construe as a recognition of their competency to serve in the Medical Corps of the Army. This implication will be pointed out by the osteopaths not only in connection with any future Congressional demands they make but also in connection with state legislation that they may sponsor.

For the foregoing reasons, it is important that state medical associations urge their senators to eliminate so much of the authorization from the bill as is underscored. If the underscored language be eliminated, the War Department will still be authorized to employ interns and may exercise full discretion in their selection.

Sincerely yours,

J. W. HOLLOWAY, JR.

## COMMITTEE ON MATERNAL WELFARE

### CASE HISTORY: FATAL DIABETES IN PREGNANCY

A thirty-year-old multipara who was seven months pregnant arrived at the hospital in active labor and in diabetic coma. Two previous pregnancies had been normal, with living children, and a third had resulted in a stillbirth. The patient was known to have had diabetes for four years; during this particular pregnancy, however, she had had no prenatal care, nor had she seen a physician for her diabetes. Besides the diabetes, the pregnancy was complicated by an "inflammation of the right leg," which may or may not have been a phlebitis. The patient arrived at the hospital at 3:45 a.m. Five minutes later, she delivered herself of a stillborn infant, and in spite of insulin and intravenous glucose to combat the coma, she did not regain consciousness and died about twenty hours after delivery.

*Comment.* It is unfortunate that details of the history are entirely lacking, but it is very evident that the pregnancy aggravated the diabetes, which was the direct cause of death. The modern treatment of diabetes in pregnancy requires very constant medical supervision. Patients with mild diabetes are unstable during pregnancy; those with severe diabetes are extremely unstable. Labor at seven months with a stillborn infant is not at all infrequent in diabetic patients, even those under excellent medical care.

Patients with diabetes may begin a pregnancy with perfect confidence so far as their own survival goes; not so with the babies. Modern treatment has decreased the infant mortality in diabetic mothers very materially, but miscarriages, premature labors and dead babies do occur, and occasionally patients go to term and deliver themselves of stillborn infants.

The death in the case presented is attributable solely to the patient herself, who consulted no physician during her pregnancy. Had she been under good medical care, that is, under specialized diabetic care, she certainly would not have lost her life, and it is very possible that the baby would have survived.

### DEATHS

HIGGINS—JAMES H. HIGGINS, M.D., of Marston's Mills, died April 7. He was in his seventy-second year.

Born in Marshfield, Missouri, Dr. Higgins received his degree from the College of Physicians and Surgeons, Boston, in 1894. He was formerly town and school physician for the town of Barnstable, and a member and chairman of the Barnstable Board of Health. He was a former president and secretary of the Barnstable District Medical Society, and a fellow of the Massachusetts Medical Society and the American Medical Association.

His widow, two sons and three daughters survive him.

**RODRICK** — ALBERT F. RODRICK, M.D., of Beverly, died April 30. He was in his seventieth year.

Dr. Rodrick received his degree from Tufts College Medical School in 1901. He was a former member of the Massachusetts Medical Society and the American Medical Association.

He is survived by two sons and two sisters.

**SISE** — LINCOLN F. SISE, M.D., of Brookline, died April 28. He was in his sixty-eighth year.

Born in Medford, Dr. Sise received his degree from Harvard Medical School in 1901. He was visiting anesthetist of the Boston City and Long Island hospitals, clinical assistant in anesthesia at Harvard Medical School and lecturer on anesthesia at Tufts College Medical School, and for many years, preceding his retirement three years ago, was the chief anesthetist at the Lahey Clinic. He was a member of the American Society of Anesthetists, and a fellow of the Massachusetts Medical Society and the American Medical Association.

He is survived by his widow, two sons and three grandchildren.

**SWIFT** — WALTER B. SWIFT, M.D., of Boston, died May 2. He was in his seventy-fifth year.

Born in Geneva, Switzerland, Dr. Swift received his degree from Harvard Medical School in 1907. Dr. Swift specialized in the treatment of nervous diseases, particularly speech defects. He was formerly associated with the Boston City Hospital, Tufts College Medical School and the Boston State Hospital. He was a fellow of the Massachusetts Medical Society and the American Medical Association.

He is survived by his widow and two daughters.

**WATSON** — FRANCIS S. WATSON, M.D., of South Dartmouth, died May 5. He was in his eighty-ninth year.

Born in Milton, Dr. Watson received his degree from Harvard Medical School in 1879. After an internship at the Massachusetts General Hospital, he studied abroad and then began the practice of surgery in Boston. During his career, he was associated with the staffs of the Boston City, Children's and Carney hospitals and the Boston Dispensary, having been surgeon-in-chief at the Boston City Hospital from 1906 to 1910. Specializing in genitourinary surgery, Dr. Watson was, for many years, in charge of this department at the Harvard Medical School and at one time was president of the American Association of Genito-Urinary Surgeons. He was honorary president of the International Urological Society, and was a member of the Massachusetts Medical Society and the American Medical Association.

His widow survives him.

## WAR ACTIVITIES

### CIVILIAN DEFENSE

#### STATE HOSPITAL OFFICER

Appointment of a state hospital officer as an official of Emergency Medical Service has been recommended by the Medical Division of the United States Office of Civilian Defense for densely populated states in the target areas. These areas are principally in the First, Second, Third, Fourth, Eighth and Ninth defense regions.

The principal function of the hospital officer will be the planning of emergency base hospitals for the reception of

civilian casualties and other hospital evacuees. An official memorandum sets forth his duties as follows:

1. To survey the hospitals throughout the state (excluding those in the exposed cities), to determine how many beds can be put into immediate use in emergency with existing kitchen, laundry, sanitation and other engineering facilities
  - (a) By clearing patients to their homes.
  - (b) By restricting admissions.
  - (c) By use of rooms not normally used for patients.
  - (d) By rehousing medical and nursing staff and other hospital personnel outside the hospital.
  - (e) By use of neighboring buildings (schools, hotels and so forth) for patients (or staff).
  - (f) By extra bed accommodation in temporary structures erected on available grounds adjacent to the hospital.
2. To assist in designating, for each casualty hospital or group of hospitals in each exposed city,
  - (a) The line of evacuation to the base.
  - (b) The transport arrangements.
  - (c) The emergency base hospitals provisionally allotted to each casualty unit.
3. To keep constantly informed of the bed state of every hospital in his area by weekly returns.
4. To advise the Office of Civilian Defense, through the regional medical officer, on the need for providing additional accommodations, for example, by temporary construction or by converting convalescent homes, hotels, school dormitories or other structures into hospitals.
5. To report to the regional medical officer of the Office of Civilian Defense any exceptional condition requiring action (for example, matters beyond state boundaries, or required by the needs of the military situation) and to forward to him copies of a monthly summary report on the state's emergency hospital program. Where a hospital outside a state boundary is readily accessible for the reception of casualties from an exposed city, this fact should also be noted.
6. To maintain constant touch with the other service departments of the state defense council (for example, evacuation and so forth).
7. To supervise the distribution of medical and hospital supplies under the direction of the state civilian defense property officer and report any threatened deficiency to the regional medical officer.
8. To supervise staff arrangements for emergency base hospitals and for reception areas.
9. To control movements of medical and nursing staff, as well as of casualties, in any situation affecting emergency base hospitals.

The hospital officer must work in close collaboration with the state evacuation authority, the memorandum points out. In addition, he may find it necessary to collaborate with the state officer in charge of institutions for the care of mental patients, if such hospitals are to be used as emergency base hospitals for the reception of casualties and other patients evacuated from urban hospitals. Transport arrangements are to be handled in collaboration with the evacuation authorities of the state and the military authorities of the area.

# MISCELLANY

## MEDICAL AND SURGICAL RELIEF COMMITTEE OF AMERICA

The Medical and Surgical Relief Committee of America will distribute literature concerning its nation wide activities and sell its official emblem at the forthcoming convention of the Massachusetts Medical Society on May 26 and 27

Since America entered the war, the committee has been furnishing medical and surgical supplies to emergency field stations, needy hospitals and other recognized relief agencies throughout the country. One hundred and forty four emergency medical field sets have been supplied to defense officials in potential target areas in twenty five states of these, Massachusetts has so far received fourteen

The following Boston physicians are affiliated with the committee: Dr John D Adams, Dr Fuller Albright, Dr Arthur W Allen, Dr Bennett F Avery, Dr Ralph S Banay, Dr P F Butler, Dr Richard B Cattell, Dr Sara M Jordan, Dr Frank H Lahey, Dr C H Lawrence, Dr Ralph D Leonard, Dr Philip E Meltzer, Dr Vals Menkin, Dr Harris P Mosher, Dr Abraham Myerson and Dr Paul Dudley White. Other Massachusetts physicians in field: Dr Hilbert T Day, of Cambridge, and Dr Francis W Palfrey, of South Duxbury

## RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR MARCH, 1942

DISEASES	MARCH 1942	MARCH 1941	FIVE YEAR AVERAGE*
Anthrax or polio myelitis	0	1	0
Cholera	194	1408	1492
Diphtheria	16	8	12
Dog bites	870	655	763
Dysentery bacillary	0	3	101

## GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Anthrax was reported from Boston, 1, Haverhill, 2, total, 3  
Diphtheria was reported from Adams, 1, Boston, 2, Fall River, 2, Lowell, 2, Medford, 1, Somerville, 2, Springfield, 2, West Brookfield, 1, Wrentham, 3, total, 16  
Encephalitis, infectious, was reported from Belmont, 1, Boston, 1, Pittsfield, 1, total, 3  
Meningitis, meningococcal, was reported from Ashby, 1, Boston, 6, Brookline, 2, Cambridge, 1, Camp Edwards, 1, Canton, 1, Chelsea, 3, Fall River, 1, Lowell, 1, Marlboro, 1, Melrose, 1, Milford, 1, North Adams, 1, Springfield, 2, Quincy, 1, Worcester, 3, total, 27  
Meningitis, other forms, was reported from Boston, 1, Brockton, 3, Cambridge, 1, Canton, 1, East Bridgewater, 1, Gloucester, 1, Hampden, 1, Holyoke, 2, Lawrence, 1, Lexington, 1, Lowell, 1, Medfield, 1, Needham, 1, Northampton, 1, Quincy, 1, Revere, 2, Salem, 1, Somerville, 1, Springfield, 1, Watertown, 1, Wellesley, 1, total, 25  
Septic sore throat was reported from Boston, 12 Brock-

ton, 1, Cambridge, 3, Marlboro, 1, Medford, 2, Merrimac, 1, Millbury, 1, Newburyport, 2, Northampton, 2, Quincy, 1, Stoughton, 1, Waltham, 1, Worcester, 3, total, 31  
Tetanus was reported from Haverhill, 1, total, 1  
Trichinosis was reported from Boston, 2, Wakefield, 1, total, 3

Typhoid fever was reported from Boston, 2, total, 2  
Undulant fever was reported from Greenfield, 1, Uxbridge, 1, total, 2

Typhoid fever and tuberculosis, other forms, struck record low incidences this month

Anterior poliomyelitis, bacillary dysentery, paratyphoid fever, undulant fever, whooping cough and lobar pneumonia were reported at figures below the five year averages

Dog bites reached a record high figure this month  
Mumps, following a months drop from record figures, is again reported at record high incidence

Chicken pox, diphtheria, German measles, meningococcal meningitis, scarlet fever and pulmonary tuberculosis were reported at figures above their five year averages

Cases of animal rabies were reported in Tewksbury and Burlington, maintaining the focus in the northern section of the State (Middlesex County)

## VICE-PRESIDENT OF PHARMACEUTICAL FIRM DIES

Malcolm Galbraith, vice president and director of sales of the Upjohn Company, died April 10 in Kansas City. Mr Galbraith was born in Bowmanville, Ontario, Canada, October 23, 1876. He received his bachelor of pharmacy degree at Ontario College of Pharmacy in 1898, entering the drug business in Ontario the same year. He later became a naturalized citizen of the United States. In 1909, he left the H. K. Mulford Company, of Philadelphia, to join the Upjohn Company. In October, 1929, he was elected to the board of directors and named director of sales. He was made vice president of the company in May, 1936

## NOTES

Four promotions at the Harvard Medical School, effective July 1, were recently announced. Dr John H Mueller, associate professor of bacteriology and immunology, has been named professor of bacteriology and immunology, he will take charge of the department at the Medical School and also at the School of Public Health.

The following men were named to associate professorships: Dr Fuller Albright, now assistant professor of medicine, Dr Allan M Butler, now assistant professor of pediatrics, and Dr Hiram H Merritt, now assistant professor of neurology. In addition, Dr Frederick J Stare has been appointed assistant professor of nutrition effective July 1

Dr William Dameshek, assistant professor of medicine at Tufts College Medical School, was recently appointed professor of clinical medicine.

The Committee on Faculty of Middlesex University recently announced the appointment of two new full time teachers to the faculty of the School of Medicine, for the school year starting July 1, 1942. Dr Fritz Schweinburg has been appointed professor of bacteriology. Born in Vienna, Dr Schweinburg received his medical degree from the University of Vienna in 1908, served as assistant pathologist under Professor Sternberg till 1910 and as temporary head of the Department of Medicine at the Rudolfs hospital in Vienna until 1916. During World War I,

he served in the Austrian army as head of an epidemic hospital, and then became a member of the staff of the Pasteur Institute of Vienna and head of that institution from 1934 to 1938. Dr. Peter Gruenwald has been made assistant professor of histology and embryology. Born in Bohemia, Dr. Gruenwald received his medical degree from the University of Vienna in 1936, and was associated with the histological department of the university until he came to the United States in 1938.

## CORRESPONDENCE

### PROTECTION FOR PHYSICIANS IN THE ARMED FORCES

The following sentences made the last two paragraphs of my presidential report read at the annual meeting of the Middlesex South District Medical Society on April 22, 1942, and I hope that the ideas contained in them may help others:

Your officers are very much aware of the fact that this is a war year and that many of our fellows are young and in good health and so are privileged to serve their country conspicuously, as we all should be glad to do. We wondered if some kind of round robin pledge to those in service could be sent from us who remain at home concerning our attitude in regard to the patients of those who go, but after talking with many members of our society, we decided against such action. We can assure those who go that it is the general desire that they will find loyal patients and consultants when they return to civil life. We believe that this will best be accomplished if those who go into the service make definite arrangements for the referral of patients from their homes or offices to a doctor or group they trust so that their patients will be cared for in an approved way and returned to them on their return to practice.

Finally, it is the hope and desire of your officers that if during the war any crisis, financial or otherwise, arises in the family of the doctors who serve away from home, that the family will let the president of this *their* medical Society know promptly, for your officers know ways of helping and pledge themselves to investigate and help quickly. Later I hope to write this desire of ours to each one individually.

HILBERT F. DAY, *President*  
Middlesex South District Medical Society

412 Beacon Street  
Boston

### "AMERICAN INSTITUTE FOR PSYCHOANALYSIS"

*To the Editor:* In an editorial entitled, "American Institute for Psychoanalysis," published in the April 16, 1942, issue of the *Journal*, several statements are made which we feel ought to be answered. The editorial refers to the fact that a group of members and students of the New York Psychoanalytic Society and Institute resigned within the last year as a protest against what they termed "dogmatism in psychoanalytic education" and established an Association for the Advancement of Psychoanalysis and an American Institute for Psychoanalysis. At the same time, they emphasized the difference between what they termed "classical" and "non-classical" training in psychoanalytic theory and practice.

In reply to the announcement of this group, the New York Psychoanalytic Society and Institute emphasized,

among other things, that its records showed "differences in theoretical and technical viewpoints were the issue which led to these resignations," but "they curved only because, within the Institute as a whole, dissident group violated academic freedom by attempting to maintain an exclusive influence on the education of a small group of students" and "this could not be permitted."

In the editorial, it is stated that "a justifiable criticism of some psychoanalysts of the Freudian school or of some of the psychoanalytic societies is that they insist on orthodoxy, the incontrovertible correctness of Freud's fundamental concepts." We would like to emphasize that such a statement is not borne out by what we know of the scientific and historical development of psychoanalysis.

Freud's work cannot be understood unless its progress is followed through his various publications, thus obtaining a coherent picture, as in all the fundamental sciences of the evolution of psychoanalysis from its early beginnings. The alleged changes in psychoanalysis, as emphasized by its opponents, have not overthrown the original concepts and discoveries, for what has taken place is essentially a new development or viewpoint as fresh theories are explored through accumulating clinical experiences.

A few statements will help to clarify our attitude. For instance, an editorial preface to the English translation of Freud's *Collected Papers* states: ". . . his [Freud's] path lay through a jungle hitherto completely unexplored. Rarely did his path follow a straight line for long; deviations, detours, fresh departures were often necessary, and occasionally even the retracing of his steps." One of Freud's most important modifications concerned his changed attitude on the importance of sexual traumas in childhood, since he discovered that it was not necessary for them to be actual experiences, but might be in many instances related only to the fantasies of the individual. In a paper published in 1905, entitled "My Views on the Part Played by Sexuality in the Aetiology of the Neuroses," he emphasized that, as a result of more extensive clinical experience, he was able to correct the most momentous of his early errors, thus necessitating a change in the conception of the mechanisms of hysterical symptoms.

Furthermore, in Freud's revision of the anxiety problem in 1926, which is so important for an understanding of the neuroses, he again showed that he was not an entrenched advocate of scientific dogmatism. For instance, he states, "Anxiety causes the repression, and not, as I earlier stated, the repression the anxiety." In his *Autobiography*, too, he writes, "The science of psychoanalysis is seldom able to deal with a problem completely, but it seems destined to give valuable contributory help in a large number of regions of knowledge."

These changing viewpoints of Freud, in both theory and technique, took place under the pressure of widening and deepening experience, and the attitudes of both Freud and the psychoanalysts of the Freudian school are free from dogmatism and show a willingness to change theories in the light of broadening knowledge. Many of these analysts have introduced new techniques as modifications of the original basic theories.

The viewpoints of this dissident group do not appear to us as revolutionary as many uninformed persons might be led to believe; consequently, their insistence on the dogmatism of the so-called orthodox Freudians will not bear critical investigation.

We should also like to draw your attention to an editorial in the September 21, 1939, issue of the *Journal*, en-

itled 'The Organization and Development of the Psychoanalytic Association,' on the occasion of the publication of the *Bulletin of the American Psychoanalytic Association*, which states in part: "It shortly became evident that meticulous training in psychoanalysis was essential to an adequate understanding of this method of treatment. In view of this, the association gradually altered its structure to become a federation of local psychoanalytic societies, each local society admitting only physicians with adequate training."

The American Psychoanalytic Association has set a high standard of organization. Through the local societies it exerts a wide influence. It is to be congratulated not only on the standards it has set but also on the care that has been used in selecting members. The first number of its bulletin, giving the details of the organization, is a valuable historical document.

We can only hope that the American Psychoanalytic Association will continue with its high standards in the selection and training of its members. Perhaps the organization of a secessionist group is in itself a proof of how high the standards actually are.

ISADOR H. CORIAT, MD, *President*  
Boston Psychoanalytic Society

M. RAIPH KAUFMAN, MD, *Chairman*  
Educational Committee, Boston Psychoanalytic Institute

## REPORT OF MEETING

### GREATER BOSTON MEDICAL SOCIETY

A regular meeting of the Greater Boston Medical Society was held at the Beth Israel Hospital on January 6. Dr Samuel Gargill presiding. Dr Alan I. Guttmacher, of Johns Hopkins University School of Medicine, discussed 'Spontaneous Abortions and Malformed Children. What can be done about them?'

The speaker first considered causes of abortions and what may be done to decrease the incidence. The amount of physical exertion allowed by physicians is variable but Dr Guttmacher permits any activity in which the patient is accustomed. The only restriction is long automobile rides during the first sixteen weeks, such trips by other methods are not forbidden. This too, which is admittedly a throwback to the days of automobiles and rough roads, probably has no real basis in the present era. An inherent germ plasm defect is the most commonly recognized cause of abortions of the spontaneous variety. Here there is nothing to save. There may be an abnormal embryo or phoblast or both, or any degree of the combination of spontaneous abortions from this cause have been roughly estimated from 75 to 85 per cent.

The course of most abortions is fairly constant. There is a normal growth for several weeks before the fetus is to develop, then it dies, and is passed several weeks later. The last episode probably takes place about six weeks after death, which means that the pathologic ovum is but a relatively short time. Abortions in normal species usually occur later. Failure to be fertilized or to develop normally is common to all mammalian ova. It has been estimated that in monkeys there are 24 per cent more corpora lutea than embryos and that there is a 1 per cent loss in the opossum. Usually a germ plasm defect causes this failure of fertilization. Possible causes suggested by analogy include defective genes or chromosomes, or both for it is known that all mammals have defective genes but that the results are apparent

only if sperm and ovum have the same defect, faulty intrauterine mechanism, for many factors are essential to the implantation of the ovum and the setting up of adequate nutrition, and improper intrauterine environment in the form of oxygen, hormones and vitamins. The causes of abortion in nonpathologic ova are also multiple placental abnormalities, such as complete placenta membranacea, placenta previa and premature separation, maternal diseases, especially of the toxic variety, but these and tuberculosis and syphilis are likelier to cause premature labor, endocrine dyscrasias, especially a lack of progesterone, laparotomies, especially if a pelvic operation is undertaken, and here the use of heavy sedation, with morphine and large amounts of progesterone, is helpful defects of the regenerative organs, but such conditions are apter to cause sterility than abortions, and the role of fibroids is certainly overrated, and psychic and physical trauma, which are usually not serious if the fetus is healthy, but may hurry an inevitable event or may be a coincidence.

It becomes apparent that the proper treatment of threatened or incipient abortions should be based on a knowledge of whether an ovum is healthy or diseased. Such facts, however, are not easily obtainable. Dr Rutherford, at the Boston Lying in Hospital, has made suction biopsies of bleeding patients and found that if necrotic deciduum is obtained abortion cannot be prevented by any means, whereas there is a 50 per cent chance of survival on expectant treatment if the biopsy is normal. Bleeding is considered an important symptom, but it was not until recently that it was learned that 21 per cent of normal pregnant women stain during the first twenty eight weeks. There was no characteristic difference in the bleeding, except that the passing of clots and the presence of uterine cramps were noted in only one of those who did not abort, whereas these findings were common in those who aborted. Vomiting may prove a valuable prognostic aid, for those who eventually aborted had only half the nausea and vomiting experienced by the control patients. Hormonal studies on prolactin and pregnandiol levels are of no importance unless there is a consistently negative Friedman test and repeated quantitative determinations are made. The constantly increasing size of the uterus is a good sign, whereas a decrease in the size of the breasts and a loss of weight in the presence of a good appetite after the fourth month are bad omens.

Treatment varies with the symptoms. For staining, rest and abstinence from coitus for two weeks are advised. With frank bleeding bed rest is demanded as well as vitamin E and progesterone. Examination for a local cause is carried out after one week, and it is usually possible after ten days to predict the outcome. The absence of nausea and vomiting is considered an unfavorable sign, and no treatment is given except advice unless the patient demands it. The onset of cramps requires immediate hospitalization for the event is then about twenty four hours away. If the cervical os is open, immediate dilatation and curettage are carried out. All products should be saved at all costs, both to determine the totality of the abortion and to evaluate the viability of the fetus, so that advice may be given for future pregnancies. If the ovum is abnormal, a new attempt at conception is suggested in two weeks. Thyroid extract is administered for a few weeks if the basal metabolic rate is depressed, for this may stimulate the hormonal system and foster better intrauterine conditions. If the ovum is normal the patient should be thoroughly examined and put in the best possible condition. It is then advised that conception should

not be attempted for a six-month interval, to allow for a correction of the unknown cause. The condition of the husband is considered of little importance.

Abortions should not be considered habitual unless there are more than three successive ones, because any less than that number may be merely on the law of averages or from random causes. There is a high incidence of spontaneous cures among the cases with random causes, which comprise by far the largest group. Less than 1 per cent of cases occur in women who have had more than three abortions. And in this group, there are few if any tested cures. In the treatment of threatened abortion in suspected patients, bed rest is vital. In addition, the administration of progesterone may be started four weeks before the time of the anticipated abortion and continued until four weeks from term. Antuitrin may be employed in the hope of perpetuating the existing corpus luteum.

Congenital malformations seem to be related to germ-plasm abortions and sterility, for they are all considered evidence of regenerative inefficiency. These malformations often follow a long period of sterility or a recent abortion. Furthermore, there is a high incidence of abnormal offspring in pregnancies in which threatened abortion has been treated with progesterone. The wisdom of such therapy is therefore again questioned.

The discussion was opened by Dr. Harold Rosenfield, who is still very cautious in the prenatal restriction of his patients because of the danger of criticism in the event of an abortion. When staining occurs, he advises complete bed rest until two days have passed without any show and carries out other measures, such as the administration of hormones and wheat-germ oil. In the prophylaxis of abortions, he has found that 35 per cent may be attributed to defective sperm, and he studies the husband, especially from the standpoint of fatigue.

Dr. Arthur Hertig, in discussing habitual abortions, stated that this is apparently not a different group, for there is the same variety of causes as in any group. But any given habitual aborter is prone to repeat the same complex. He has never seen an abortion caused by trauma. The causes of abortion are 70 per cent fetal, 46 per cent being accounted for by true "blighted ova." A study of embryos as early as the eleventh day of gestation indicates that about 50 per cent of all ova are pathologic, so that many blighted ova may merely pass out with the next menstrual period, which may be slightly late and profuse. Bleeding at the time of implantation may simulate the first missed period and confuse calculations.

Dr. Robert Rutherford stressed the effect of circumvallate placenta in the production of abortion; this is the commonest cause of midtrimester miscarriage. Progesterone is of no therapeutic value. Intense therapy with this hormone may serve to keep a pathologic ovum in the uterus for the entire nine months, with the real danger of degeneration into a hydatidiform mole. Such patients may even retain the products of conception after a therapeutic dilatation and curettage, and thus fail to resume the normal cycle.

Dr. Saul Berman suggested that some male factor is responsible in early 70 per cent of the cases. He raised the question whether vitamin E is carcinogenic. He considers the study of the husband and of the thyroid gland to be essential in cases of habitual abortion.

In conclusion, Dr. Guttmacher stated that although the male factor may be a cause in well over 50 per cent of cases of sterility, he does not believe it to be of significance in germ-plasm abortions.

## BOOK REVIEWS

*Abdominal Surgery of Infancy and Childhood.* By William E. Ladd, M.D., and Robert E. Gross, M.D. 4°, cloth, 455 pp., with 268 illustrations and 39 tables. Philadelphia: W. B. Saunders Company, 1941. \$10.00.

This book gives the record of an era in surgery. During the last twenty-five years, pediatricians and surgeons have co-operated to reduce the mortality in many diseases of infancy and childhood that can be cured by surgery. The results are given here in actual figures and are achievement of first magnitude. The book is a masterpiece of orderliness and simplicity, and this enables the reader to understand, with a minimum of effort, the basic principles underlying each disease.

The conditions dealt with are surgical affections of the abdomen and genitourinary tracts. As the authors emphasize, it is not fitting that one consider the infant a small adult, for in the category of congenital diseases no counterpart is found in older patients. Furthermore, in diseases common to young and old alike, a reduction of mortality in the former has been possible only by methods other than those used for the older group. Surgeons who operate on infants and children must therefore adopt a different set of standards for such patients, and this book is an excellent guide to exact diagnosis and proper therapy.

The very striking record at the Children's Hospital in the treatment of appendicitis in childhood makes this chapter alone worth the price of the book. The surgeon, pediatrician and general practitioner will all find the book of value in their practice.

*The Man Who Lived for Tomorrow: A biography of William Hallock Park, M.D.* By Wade W. Oliver, M.D. 8°, cloth, 507 pp., with 1 portrait. New York: E. P. Interton and Company, Incorporated, 1941. \$3.75.

This biography of the pioneer leader in bacteriology applied to public health, whose labors in the diagnostic field in the early days of the New York Health Department afforded a stimulus to laboratory procedure throughout America, is a charming and friendly account of the man and his work. Park's work on the laboratory diagnosis of diphtheria, published in 1893, was the first large-scale, intensive attack on the carrier problem and started a development that grew into a model city health department. Other work followed in order: smallpox vaccination, diphtheria antitoxin, the examination of milk by the Schick test and much else. Park was an indefatigable worker and set a high standard for himself and his colleagues. He is honored by a fitting and well-written biography.

*Vocational and Professional Monographs. No. 4. Medicine.* By Dwight O'Hara, M.D. 8°, paper, 27 pp. New York: Bellman Publishing Company, Incorporated, 1941. 50c.

This small brochure is addressed to college men who are considering entrance into the medical profession as a career. It is full of sound advice and the necessary facts that are needed in making the decision. The professions are clearly set forth in a readable, businesslike style. The material deserves a better format, for the author has created an exceptional essay, full of sound common sense. Apt quotations enliven the statistics, and many a man ready in the profession could read this little book with profit and pleasure.

## SARCOMA OF THE BREAST

### A Report of Twenty-two Cases

HORATIO ROGERS, M.D.,\* AND SPENCER FLO, M.D.†

BOSTON AND GREENFIELD, MASSACHUSETTS

RECENT studies show that sarcoma constitutes between 2 and 3 per cent of all malignant tumors of the breast, but since the medical literature of the past eighty years records less than 600 cases,<sup>1</sup> it seems that the diagnosis is often missed.

The combined records of the Pondville Hospital (Massachusetts Department of Public Health) and Massachusetts General Hospital back to 1923 contain 22 cases of breast sarcoma with reliable pathological diagnoses and follow-up notes. All 22 patients were women between the ages of eighteen and sixty-nine, and the average age was forty-four years. Comparable figures in a group of 60 patients treated at the Johns Hopkins Hospital from 1894 to 1934 give forty-nine years as an average age, with a range of thirteen to seventy-five years<sup>2</sup>; there were 2 male patients.

#### Classification

The terminology resulting from different pathological classifications is confusing to the surgeon. A practical and comparatively simple classification is suggested by Fox,<sup>2</sup> who divides all breast sarcomas into four groups as follows:

#### Group I. Fibrosarcoma

- (a) Fascial type (spindle-cell sarcoma, periductal angiosarcoma and fibrosarcoma)
- (b) Secondary to adenofibroma (adenofibrosarcoma)
- (c) Secondary to intracanalicular fibromyxoma (periductal myxosarcoma,<sup>3</sup> fibromyxosarcoma and cystosarcoma)

#### Group II. Neurogenic sarcoma (perineural fibrosarcoma and melanotic sarcoma)

#### Group III. Lymphoid and myeloid sarcoma (round-cell sarcoma)

#### Group IV. Miscellaneous nonindigenous sarcomas (giant-cell sarcoma, carcinosarcoma, angiosarcoma, liposarcoma and so forth)

Group I (fibrosarcoma) is by far the largest, containing 82 per cent of our cases and 70 per cent of those at the Johns Hopkins Hospital. The individual tumors in this group vary somewhat in degree of malignancy, but their clinical behavior is fairly constant and comparatively favorable. They tend to form large bulky tumors, to grow into contiguous structures by direct extension, not to metastasize to regional lymph nodes and not to invade the blood stream until late, if at all.

The other groups are less important because they include so few cases. The neurogenic sarcomas and the lymphoid and myeloid sarcomas are characterized by a high degree of malignancy and a fatal outcome. There are rapid growth, early metastasis to regional lymph nodes (especially in the lymphoid and myeloid types), early blood-stream invasion and early remote metastasis. The last group contains miscellaneous rare tumors whose behavior shows no group characteristics.

In Table 1, our 22 cases are compared with those reported by Fox. Approximately one third of the patients in both series are known to be dead of sarcoma, the two mortality rates being strikingly similar. The rate of curability is less accurate, since it is based on an arbitrary time limit of five years. On this basis, the curability for our series of 22 patients is not lower than 36 per cent, and that for the 18 patients in Group I (fibrosarcoma) is not lower than 44 per cent. A scrutiny of our 6 indeterminate cases shows that at least 3 are likely to be cured; this will raise the curability figures to 50 and 60 per cent, respectively. It is recognized that our figures are too small for the derivation of significant percentages.

\*Instructor in surgery, Harvard Medical School; associate visiting surgeon, Massachusetts General Hospital.  
†Formerly, resident surgeon, Pondville Hospital.

All 4 of our patients outside Group I died of sarcoma. To what extent this mortality rate should be ascribed to inadequate treatment and how accurately it reflects the fatal nature of the disease

TABLE 1. *Tabulation of Cases.*

TYPE	STATUS OF PATIENT	OUR CASES	FOX'S CASES
Group I (fibrosarcoma)	Dead of sarcoma	4 (22%)	10 (24%)
	Living and well at 5 years	8 (44%)	14 (33%)
	Living and well under 5 years	6	18
	Totals	18	42
Group II (neurogenic sarcoma)	Dead of sarcoma	0	3
	Living and well at 5 years	0	0
	Living and well under 5 years	0	4
	Totals	0	7
Group III (lymphoid and myeloid sarcomas)	Dead of sarcoma	1	5
	Living and well at 5 years	0	0
	Living and well under 5 years	0	2
	Totals	1	7
Group IV (miscellaneous sarcomas)	Dead of sarcoma	3	1
	Living and well at 5 years	0	0
	Living and well under 5 years	0	3
	Totals	3	4
All groups	Dead of sarcoma	8 (50%*)	19 (58%*)
	Living and well at 5 years	8 (50%*)	14 (42%*)
	Living and well under 5 years	6	27
Grand totals		22	60

\*These percentages take no account of the cases followed for less than 5 years

itself cannot be determined. It will be noted that the Johns Hopkins series also shows no five-year cures outside Group I.

The treatment of these 4 cases happened to be inadequate. Two patients had local excision of small tumors, one of which proved to be a lymphoid sarcoma, and the other, a carcinosarcoma. The former refused further surgery and, after temporary improvement with x-ray treatment, died of multiple generalized metastases within six months. The latter died of metastases to the ribs, lungs and brain twenty months after a fruitless radical mastectomy undertaken after an unexplained delay of ten months. Both the remaining 2 patients had large angiosarcomas, one with known lung metastases. Palliative simple mastectomy was done for both. One died in two years of generalized metastases, and the other in six months of metastases to the lymph nodes and lungs. Thus, no conclusions concerning the possible ef-

fectiveness of ideal treatment can be drawn from these 4 cases.

A consideration of the treatment of the 18 cases in Group I (fibrosarcoma) is more instructive. Of 2 patients who had local excision of small tumors, one is alive after sixteen years, and the other, although she has survived operation for only four and a half years, is probably cured since no tumor tissue could be found when a wide excision of the scar was done ten months after the original operation.

Of the 11 patients treated by simple mastectomy, the 4 whose tumors were small (under 7 cm.) are alive—2 for over five years and 2 for over two years. A fifth patient with a tumor of unrecorded

FIGURE 1.

*This sixty-four-year-old patient had had painless swelling of the breast for nine months. The pathologist reported "adenofibrosarcoma." The patient was living and well five years and three months after simple mastectomy.*

size had simple mastectomy followed in two years by local recurrence in the form of a tumor 26 cm. in diameter. This was radically excised, and the patient is living and well three and a half years later (five and a half years after simple mastectomy). Of the remaining 6 patients, whose tumors were large (10 to 30 cm.), 3 are living after ten, five and a half, and two years, respectively. The other 3 died, 1 in two years of extension to pleura, 1 in two years of bone metastases, and 1 in six months of pulmonary metastases.

Radical mastectomy was undertaken as a primary procedure in only 4 cases. The 2 patients

whose tumors were small are alive and well after nine and seven years, respectively. Of the 2 patients whose tumors were large, one is alive for four years; the other was subjected to radical

FIGURE 2.

*This thirty-three-year-old patient had had painless swelling of the breast for about seven years. The pathologist reported "fibrosarcoma of breast and benign hyperplasia of lymph node." The patient was living and well two years after simple mastectomy, with lymph-node biopsy.*

mastectomy on the chance that a suspicious area of bone destruction in the jaw might prove to be unrelated to her disease, but she died six months later with metastases to the jaw and scapula. It is

FIGURE 3.

*This sixty-year-old patient had had a simple mastectomy for painless swelling of six months' duration, associated with trauma to the breast. The pathologist reported "adenofibrosarcoma." Nine months later, a radical operation was done for local recurrence, and the photograph shows a second recurrence twenty months after the last operation.*

significant that the axillary lymph nodes were not affected in all 4 cases.

Finally, 1 patient whose operation is not well enough described to be classified lived ten and a half years and died of other causes.

### Treatment

In an evaluation of the results of treatment in these 22 cases, the most striking conclusion is as follows: for patients in Groups II (neurogenic), III (lymphoid and myeloid) and IV (miscellaneous), the only hope of cure lies in radical mastectomy and axillary dissection before bloodstream and lymphatic invasion has occurred.

It appears equally clear that this is not true of patients in Group I (fibrosarcoma). There is

FIGURE 4.

*This photograph of the patient in Figure 3 was taken eight months after a block excision of the chest wall, including three ribs and a portion of the pleura. There is a third local recurrence. The patient died four months later from extension of the tumor into the pleural and peritoneal cavities.*

evidence that axillary dissection is not necessary in this group. In none of our 18 cases were lymph-node metastases demonstrated, whereas unaffected lymph nodes were found in 9 cases. Furthermore, 6 patients whose axillary nodes were not removed are still alive. On the other hand, it seems unwise to rely on either local excision or simple mastectomy for cure. Since death from tumors of the fibrosarcoma group is due to extension of the tumor into fascia or blood vessels, at least the pectoral fascia and preferably the pectoralis muscle should be removed, as well as the breast. This procedure, which would have added little to the risk of simple mastectomy, would probably have prevented 2 of our 3 deaths and obviated a massive local recurrence in another case.

Undoubtedly the reason so-called "palliative simple mastectomy" is so often done for enormous tumors of the breast is that the surgeon is thinking in the more familiar terms of carcinoma, and it does not occur to him that so large a tumor could possibly be curable. Six of our Group I (fibrosarcoma) patients presented this picture and received this treatment, some with the preoperative diagnosis of "advanced cancer of the breast." Three are apparently cured, in spite of an inadequate operation. There is good reason to think that 5 of the 6 might have been cured if a curative rather than a palliative operation had been done.

### Diagnosis

The diagnosis of breast sarcoma depends on microscopic examination. Even for the pathologist, it is not always easy to recognize the different types of malignant tumor or even to tell whether a tumor is malignant or benign. All that the surgeon can do is keep in mind the possibility of sarcoma and remember that not all large tumors are incurable. A large tumor, particularly in the absence of palpable axillary nodes, is probably either a comedo carcinoma, benign tumor or fibrosarcoma. Neither the patient's age nor a story of trauma has any diagnostic value. The story of a small tumor that after having been the same size for several years suddenly begins to grow larger is suggestive of fibrosarcoma, but is not diagnostic. The presence of cystic areas, bluish discoloration of the skin and conspicuous dilated veins over a large, lobulated tumor is almost pathognomonic of sarcoma.

### Prognosis

In 8 fatal cases, the average duration of life after operation was seventeen months, the shortest three months, and the longest forty-one months. The average time from onset of symptoms to death was twenty-seven months, the shortest six months, and the longest forty-seven months.

No definite correlation can be found between prognosis and age, nor does the duration of symptoms furnish any reliable aid. The type of tumor appears to be of the greatest significance, tumors of the fibrosarcoma group offering the best prognosis; Group III (lymphoid and myeloid sarcoma) tumors offer the worst, and tumors of the other groups are in between.

The size of the tumor appears to have prognostic significance only in Group I (fibrosarcoma). With tumors less than 5 cm. in diameter, the ratio of dead to living patients was 0.5; between 5 and 10 cm., it was 1:3; and between 10 and 30 cm., it was 3:8.

### SUMMARY AND CONCLUSIONS

Twenty-two cases of breast sarcoma are reported, with a discussion of their classification, treatment and results.

Of 18 patients (82 per cent) whose tumors were classed as fibrosarcomas, 8 (44 per cent) are known to be cured for at least five years, 6 are living under five years, and 4 are known to be dead of sarcoma. Of 4 patients whose tumors were classed as lymphoid sarcoma, angiosarcoma or carcinosarcoma, all are known to be dead of sarcoma.

The treatment of choice for tumors of the fibrosarcoma type is surgical removal of the breast and pectoralis major muscle, without dissection of the axilla. If the tumor is small and has not invaded the blood stream, the prognosis is excellent.

The only possibility of cure for the other types of sarcoma is by early radical mastectomy with axillary dissection. Regardless of the size and short duration of the tumor, the prognosis is poor unless the tumor is a fibrosarcoma.

## PNEUMONIA: A STUDY OF ONE HUNDRED AND THIRTY-TWO CASES TREATED IN THE HOME WITH SULFATHIAZOLE<sup>1</sup>

JOSEPH ROSENTHAL, M.D.,<sup>†</sup> WILLIAM A. MACCOLL, M.D. ‡ AND JOSEPH H. PRATT, M.D. §

BOSTON

**D**URING the winter of 1940-41, 132 patients with pneumonia were treated in their homes by the Domiciliary Medical Service of the Boston Dispensary. This free service by the Boston Dispensary was established in 1796 for care of the indigent sick in their homes. In a discussion of this service, Wing<sup>1</sup> states

The burden of home care of the sick who are unable to employ a physician is usually a responsibility of the local rather than of the state or federal government. It is commonly exercised as a function of the Public Welfare or Poor authorities rather than of medical institutions. Boston, unlike other cities of the country, has never employed city physicians for this purpose but has accepted the services of privately supported medical charity as a substitute.

The physicians on this service have two or more years of postgraduate hospital work and are appointed as fellows in medicine for one year. They spend their mornings in the Out Patient Department, and their afternoons, in making home visits. Their work is supervised by a full time physician who also acts in the capacity of consultant. Approximately 50,000 visits are made annually.

During the winter months, many cases of pneumonia are seen, and in the past, because of inadequate home facilities for the treatment of pneumonia then available, it was necessary to hospitalize most of these patients. This, no doubt, threw an additional burden on the already overcrowded hospitals in Boston. With the introduction of the sulfonamides, it seemed reasonable to believe that many of these patients could be successfully treated in their own homes. This led to the formation of the Pneumonia Service, consisting of four district physicians particularly interested in this work. These men were made available during and after their regular hours to study and treat patients in whom a diagnosis of pneumonia was made. Two physicians were designated to care for adults, and two for infants and children.

### METHODS

All cases of pneumonia or suspected pneumonia seen by the district physicians were referred through the district office to the physician on the Pneumonia Service, who visited the patient within a few hours. If the diagnosis of pneumonia was confirmed, the following course was instituted: the history was taken, and physical examination was made for corroboration of the diagnosis, sputum was obtained for typing, nose or throat swabs being taken in children, leukocyte and erythrocyte counts, and hemoglobin estimations were made, and blood films for differential counts were taken, a blood culture was obtained, and a urinalysis was made.

Following this, the treatment was begun at once. The drug chosen was sulfathiazole, because of its effectiveness and slight degree of toxicity.<sup>1-3</sup> It was assumed that patients were likely to follow the treatment carefully if such distressing symptoms as nausea and vomiting were eliminated. In most cases, an amount of sulfathiazole sufficient for twenty-four hours was supplied by the physician, and the first dose was usually administered in his presence.

The dosage in pneumonia in adults was 4 gm (60 gr) as an initial dose, followed by 1 gm every four hours, day and night, until the patient's temperature had been normal for seventy-two hours, although in some cases this was reduced to 1 gm every six hours during the afebrile stage, after which the drug was discontinued. In children, the initial dose was 0.065 gm (1 gr) per pound of body weight. Following this, a daily dosage of 0.065 gm per pound was administered daily, divided into six equal parts given every four hours, day and night, until the temperature had been normal for thirty-six hours, when the drug was discontinued.

Fluids were forced during the administration of the drug. Patients were instructed to take 3000 cc (3 quarts) of fluid daily. The output was followed. If the urine fell below 1500 cc in twenty-four hours, the cause was investigated, and additional fluid given. Recommended fluids consisted of stimulants, such as coffee, tea and Coca Cola, fluids high in carbohydrate, such as fruit

<sup>1</sup> Sputum and blood cultures were examined in the Bacteriology Laboratory of the Massachusetts Department of Public Health.

juices, and mineral-containing liquids, such as broth, soup and bouillon made from cubes (each cube containing 2 or 3 gm. of salt). In children, a simple mixture of 3 tablespoonfuls of carbohydrate (sugar, Karo and so forth) and 1 teaspoonful of salt in 500 cc. (1 pint) of water was used to give approximately 5 per cent glucose and saline.

The patients were followed daily until complete recovery. If residual chest signs persisted, the patient was referred to the Out-Patient Department for a roentgenogram of the chest. After careful consideration, it was decided not to determine the blood sulfathiazole levels, and our experience shows that it was not necessary.

Supportive treatment consisted mainly of high-calorie diets, sedation for chest pain, general nursing care and, not the least important, the tender ministrations of the patient's own family. The assistance rendered to the patients and the district service by the Community Health nurse in this respect cannot be too highly praised. No oxygen, digitalis or artificial stimulants were used during the course of home treatment.

RESULTS

Age

The ages ranged between two months and eighty-six years. Approximately half the patients were below the age of twelve; 23, or approximately 17 per cent of the entire group, were above the age of fifty. Three patients were between eighty and ninety years of age.

Sex

Seventy-four (56 per cent) of the entire group were males, and 58 (44 per cent) were females.

Duration of Illness before Treatment

In pneumonia, the value of early treatment needs no comment. Because in most cases the patients were seen early, the treatment could be

TABLE 1. Duration of Illness before Treatment.

instituted as soon as the physician on the Pneumonia Service had confirmed the diagnosis of the attending physician. Table 1 shows that in the majority of cases the treatment was instituted with-

in forty-eight hours after the onset of the illness; 9 patients were treated within twelve hours of the onset. Such factors as objection to hospitalization, family consultation, arrangements for care of children, waiting for ambulances and the necessary delay in examination and admission to the hospital are eliminated by home treatment.

Typing of Sputum

Pneumococci were found in the sputum of 70 cases (53 per cent) of the total of 132. In some patients who showed no pneumococci in the first sputum examination, a second sample was obtained, but this was positive in only 1 case. Table 2 shows the distribution of positive sputums by

types. Sixty per cent of the patients with positive sputums were above the age of twelve years. In evaluating the clinical data, we compared the patients whose sputum showed pneumococci with those in whom none were found.

Signs and Symptoms

In general, the signs and symptoms were similar in both groups of patients. The commonest presenting symptoms in the patients with pneumococci in the sputum were pain (67 per cent), dyspnea (63 per cent), frank chills (51 per cent) and bloody sputum (33 per cent). In all but the oldest age group, the clinical appearance presented was that of an extremely acute illness.

Temperature, Pulse and Respirations

The initial temperatures, pulses and respirations showed nothing remarkable and were characteristic of the disease in most cases.

Blood Cultures

An initial blood culture was obtained in every case but 1. Positive blood cultures were present in 6 cases. In a sixty-four-year-old patient, a Type

8 pneumococcus was found in the sputum, and blood culture was negative. Examination during a relapse a few days later showed a Type 8 pneumococcus in the sputum, and another blood culture was positive for Type 8 pneumococcus. In another case, a sixty-seven-year-old man (Case 10) first seen on the seventh day of his illness, had no pneumococci in the sputum, but a Type 2 pneumococcus was recovered from the blood culture. He expired on the day after treatment was started. In another case, there was a Type 5 pneumococcus in the sputum, and a similar type in the blood. One patient had a Type 1 pneumococcus in the sputum and blood. A twenty-two-month-old child, who showed no pneumococci in the sputum but had a positive blood culture,—Type 18,—made an uneventful recovery after three days; further treatment was refused by the family at the end of this time. Another patient, a five-year-old child, who showed no pneumococci in the sputum but Type 1 pneumococcus in the blood, made an uneventful recovery after three days of treatment. The mortality of the small group of cases with positive blood cultures was 17 per cent.

#### Blood Examinations

The initial white-cell counts ranged from 2000 to more than 50,000. A leukopenia was not considered a contraindication for sulfathiazole therapy. Red-cell counts and hemoglobin determinations showed normal variations. After therapy in most cases, there was a definite drop in the white-cell count, but there was leukopenia in only 1 case. In this patient, the white-cell count fell to 3800 per cubic millimeter, with 44 per cent granulocytes after three days of treatment, but with continued therapy, the count rose to 10,700.

In Case 10, mentioned above, the initial white-cell count was 2000; a second count taken on the day after therapy was instituted showed a rise to 3400, although the patient died on that same day. No marked drop in hemoglobin or red-cell count was noticed.

#### Urinalyses

Very few complications referable to the urinary tract were observed throughout the treatment. One outstanding feature was that in 40 patients the initial urinalyses showed the presence of albumin, white blood cells, red blood cells or casts or various combinations of them. This, in almost every case, cleared up rapidly under therapy with sulfathiazole. Twenty-four patients showed sulfathiazole crystals in the urinary sediment during treatment.

One patient showed gross hematuria. Sulfathiazole was stopped, and the urine became clear after about a week. A small group of patients

showed microscopic blood, which cleared up after treatment was stopped. There were no cases of anuria, and although it was rather difficult to measure correctly the fluid intake and output, we can safely say that in none of these cases was there evidence of retention of fluid in the tissues.

#### Duration of Fever

An interesting factor to be considered is the interval between the institution of therapy and the

\*The additional 4 cases represent relapses

drop in temperature to normal. The average length of time before the temperature dropped to normal was about forty-eight hours (Table 3).

#### Total Dosage of Sulfathiazole

Two groups of patients are considered: those who showed pneumococci in the sputum, and those who did not. Furthermore, adults and children are considered separately.

It was found that in the typed cases, adults received an average of 37 gm. of sulfathiazole, and children required an average of 12 gm. In the nontyped cases, adults received an average of 23 gm., and children an average of 10 gm.

#### Duration of Treatment

The average actual duration of treatment in the home seems to be less than that in patients treated at the hospital. It is quite possible that in many of these cases at home, as soon as the patients seemed to be well clinically, there was a tendency on the part of the family to stop all medication. This apparently had little effect on the ultimate outcome of the disease.

Since there was no direct control over the administration of the drug and since family co-operation was not always complete, the physician usually gave the initial large dose before leaving the patient. Platt<sup>13</sup> has suggested that a single large dose is frequently therapeutically effective, and in several cases, this proved to be so.

The average duration of treatment—not including fatal and hospitalized cases—was 4.0 days for the adults and 3.6 days for the children who had pneumococci in the sputum; among the patients who did not have pneumococci in the sputum, the average duration was 3.8 days for adults and 3.4 days for children.

### *Toxic Symptoms*

The outstanding toxic symptom observed in these cases was vomiting, which was noted in 20 cases. It was quite evident that in some of these the vomiting was due to the disease rather than to the drug, since it also occurred before treatment. In no case did this symptom become a serious problem. Three patients had some abdominal distention, which might or might not have been due to the drug.

A papular rash on the face and trunk was observed in one case, and a nodular erythematous rash on the extremities in another. Gross hematuria occurred in 1 patient, and microscopic hematuria in a few, as mentioned above.

A rise of temperature that could definitely be attributed to sulfathiazole was not noted in any of the cases, possibly because of the short duration of treatment.

### *Complications*

One patient developed, on the third day, a pleural friction rub over the involved portion of lung. It disappeared after four days. One patient stricken with pneumonia in her third month of pregnancy made an uneventful recovery. A twenty-eight-year-old man with a Type 3 pneumococcus in the sputum who was hospitalized because of poor home conditions developed an empyema at the hospital and was treated by thoracotomy. A thirty-five-year-old man with a Type 1 pneumococcus developed evidence of fluid in the chest after a week of treatment, and this was found to be due to a serous pleurisy. He was hospitalized, and chest taps showed no evidence of empyema. He was discharged on the ninth hospital day following an uneventful recovery.

Four infants had pertussis in addition to pneumonia. One patient developed diabetic acidosis and had to be hospitalized. Altogether, 11 patients in the entire group had to be hospitalized for various reasons.

### *Deaths*

The 5 fatal cases seem worthy of individual comment.

CASE 10. W. D. (B. D. D. 88711), a 67-year-old man, was treated for cirrhosis of the liver in August, 1940, at the Boston City Hospital. This patient, who was a chronic alcoholic, was seized with pain in the right chest on the

evening of December 25, 1940, and then with fever and increase of cough. He had had a common cold for several days previously. He was first seen by a district physician on December 31. The temperature was 102.4°F., and the pulse 120. A mistaken diagnosis of influenza was made. On January 1, 1941, the temperature was 100.4°F., the respirations 40, and the pulse 140. Lobar pneumonia involved both lower lobes. The white-cell count was 2000. On prolonged examination of the smear, only 1 neutrophil, 9 lymphocytes and 2 monocytes were found. The urine contained a large trace of albumin, numerous casts and 1.4 per cent sugar. No pneumococci were found in the sputum. A Type 2 pneumococcus was grown from the blood. Sulfathiazole, begun on January 1, the 8th day of the illness, was discontinued after a day owing to the leukopenia and nephritis. This was a mistake, since the blood on January 2, after 9 gm. of sulfathiazole had been given, contained 3400 leukocytes, of which 18 per cent were neutrophils. The urine on January 2 was free from sugar. The patient died the following night.

CASE 14. J. W. (B. D. D. 111921), a 41-year-old man, complained of fever, chilly sensations and aching pains in the extremities on December 26, 1940—5 days before treatment with sulfathiazole was begun. On the following day, there was a cough, with copious tenacious brownish sputum; the patient was a chronic alcoholic, and his landlady stated that he was probably drinking throughout the early part of his illness. The temperature was 102°F., the respirations 38, and the pulse 120. Pneumonia of the right middle and lower lobes was found. A Type 5 pneumococcus was found in the sputum and blood. Since the patient failed to improve, he was sent on January 3 to the Massachusetts Memorial Hospitals, where in addition to the sulfathiazole he was given 300,000 units of antipneumococcus (Type 5) serum after a blood culture on January 3 was found to be positive. He failed to gain and died on January 14, the 26th day of his illness.

CASE 47. N. B. (B. D. D. 83850), an 83-year-old man had been under treatment for chronic congestive failure of the heart for over 2 years when, on January 12, 1941 he was seized with a shaking chill lasting 2 hours and followed by fever. When seen on the following day, he had a cough and was raising yellow sputum. The temperature was 100°F., the respirations 32, and the pulse 92. The patient was dyspneic. Bronchopneumonia of both lower lobes was found. The white-cell count was 21,100. A Type 9 pneumococcus was found in the sputum. The blood culture was negative. Sulfathiazole treatment was begun. In 24 hours, the temperature fell to 98°F., the respirations to 24, and the pulse to 74. On the following day, the patient was greatly improved, and there was no dyspnea. The temperature was 98.2°F., and the pulse 71. The temperature was normal for 5 days—from January 14 to 19. Then, there was a recurrence of fever and pneumonia. The patient died on January 24, the 13th day of his illness.

CASE 128. A. B. (B. D. D. 95716), a 79-year-old man toward the end of March, 1941, was found to have cerebral thrombosis, with increased weakness of the left side of the body and toes. He also had chronic heart failure and senility. He had had hemiplegia a year previously. On April 5, cough, fever and labored breathings were noted. On April 9, the patient was semicomatose. He was first seen on April 10, when the temperature was 100°F., the respirations 40, and the pulse 80. Pneumonia of the right lower and left upper and lower lobes was found. Treatment with sulfathiazole was begun. The total amount

given during 6 days was 40 gm. No pneumococci were found in the sputum, and the blood culture was sterile. The patient did not respond to treatment and died on April 16 the 12th day of the disease.

CASE 153. M. M. (B. D. D. 119301), a 77 year old woman was seized with a shaking chill, followed by fever and cough on January 21, 1941. The patient had had congestive heart failure during the previous year. She was first seen on January 23, when the temperature was 102°F, the respirations 32, and the pulse 100—the rate at the apex being 120. Auricular fibrillation was present. Pneumonia involving both lower lobes was found. The heart was slightly enlarged on percussion. The liver edge was felt three fingerbreadths below the costal margin. There was no sputum but a swab made from the pharynx yielded Type 5 pneumococci. The blood culture was negative. Treatment with sulfathiazole was begun on January 24. The patient was too weak to move in bed and was incontinent and semicomatose, the eyes were sunken and glazed. She was sent to the Boston City Hospital apparently moribund. She lived however, until February 7 the 20th day of her illness. Autopsy revealed a lobar pneumonia, general arteriosclerosis, cardiosclerosis and chronic pulmonary tuberculosis involving both apices.

### Response of Children

The response of infants and children to treatment in the home was especially satisfactory. Most parents were very co-operative in following directions, and the supportive measures and general care were adequately administered. The absence of the psychic trauma of removal to unfamiliar surroundings was believed to be a positive factor in the success of home treatment. The absence of abdominal distention, except in 2 infants, suggests that the emotional strain attending hospitalization may be a causative element in the development of this complication. Convalescence appeared to be a more pleasant period, and hence more tolerable, when the patient was surrounded by familiar toys and faces. No difficult problems in child management peculiar to the treatment of pneumonia in the home arose.

### SUMMARY AND CONCLUSIONS

One hundred and thirty-two cases of pneumonia were successfully treated in the home during the winter months under adverse conditions, as the total mortality (5 patients, or 3.8 per cent) indicates. Pneumococci in the sputum were obtained in 70 cases, and 6 patients had positive blood cultures.

The mortality rate for cases with pneumococci in the sputum was 6 per cent. There were very few toxic manifestations due to the drug, and no cases of hemolytic anemia or granulopenia. Few urinary complications and no fever due to the drug were noted.

This work represents a financial saving to the community of several thousands of dollars that would have been incurred if these patients had been treated in hospitals.

The study indicates that pneumonia may be treated at home by the use of sulfonamides with death rates as low as or lower than those obtained in hospital practice, provided treatment is begun early in the disease.

During the winter season of 1941 and 1942 85 additional cases of pneumonia were treated with sulfadiazine with only 1 death. That was in a seventy-five year old woman who during the course of treatment, developed marked abdominal distention was hospitalized and died on the third hospital day, a post mortem examination disclosed partial intestinal obstruction due to a carcinoma of the small bowel with extensive metastases to the lungs and liver, and massive bilateral pneumonia.

## ELECTROENCEPHALOGRAPHIC STUDIES IN CHILDREN PRESENTING BEHAVIOR DISORDERS\*

LAZARUS SECUNDA, M.D.,† AND KNOX H. FINLEY, M.D.‡

BOSTON

**I**N CHILDREN and adolescents presenting behavior disorders, the relative consequence of environmental and biologic factors in the individual case should be determined, since the more capable one is of evaluating these factors in patients, the more intelligent the therapeutic approach will be.

Smith<sup>1</sup> has found that the development of the electrocortical activity of infants follows the course of the myelinating cerebrum. The electroencephalogram can therefore be used as a valuable measure of the structural and functional maturity of the brain.

Lindsley<sup>2</sup> and Smith<sup>3</sup> have shown that the adult pattern of the electrical brain potentials is not established until late childhood or early adolescence. They have demonstrated, and we have been able to confirm, from our own studies, that there are individual variations in the age in which the adult pattern is stabilized.

Jasper, Solomon and Bradley,<sup>4</sup> in their studies of childhood behavior disorders, noted that 71 per cent of the patients had abnormal electroencephalograms. Half the abnormal tracings were found in cases in which there was no other objective evidence of cerebral dysfunction. Strauss, Rahm and Barrera<sup>5</sup> observed abnormal electroencephalograms in 59 per cent of 22 children with primary behavior disorders. Lindsley and Cutts,<sup>6</sup> from their study of "constitutionally inferior" and behavior-problem children, found the electroencephalograms different from those of normal children in three ways: high alpha cycles, with 2 to 5 cycles per second; an increase in the number of 5 to 8 cycles per second; and vulnerability of the testing pattern to hyperventilation. These studies indicate that in a high percentage of behavior-problem children, one is dealing with an immature or abnormally functioning cerebrum. Hence, the electroencephalogram may afford an objective measure of the physical immaturity of the brain.

At the Boston Psychopathic Hospital, we have obtained tracings on 143 children presenting behavior disorders (106 boys and 37 girls). Sixty-

eight were sent by the courts of Greater Boston for psychiatric study. Seventy-five were referred by physicians at the request of their parents; thirty-five of these children came from foster parents.

Of the 143 children, 125 had normal physical and neurologic findings and no history of an illness involving the central nervous system. Seven

FIGURE 1. *Percentage Distribution of Controls and Patients in Age Groups.*

had histories of head injury followed by a period of unconsciousness; 6 had histories of chorea; 3 had a questionable history of encephalitis; and 2 may have had seizures prior to the age of seven. The average intelligence quotient of the group was 87, with a range from 65 to 134. Indication of a poorly integrated personality was brought out by the number who had a history of neurotic traits (enuresis, nail biting, and walking and talking in their sleep). Ninety had one or more neurotic traits, 32 had none, and in 21 no information was given.

The influence of the child's position in the sibling group did not seem to play a very significant role, for just as many occupied an intermediate

\*This work was supported from grants by the Scottish Rite Mason Fund and the Proctor Fund, Harvard Medical School.

§Instructor in psychiatry, Harvard Medical School.

position as those who were the oldest, youngest or only child.

The family background revealed only 18 normal families. Of the 143 patients, 16 had psychotic parents, 4 had a family history of epilepsy, and 76 came from homes broken because of desertion, divorce or death of parents, 36 of the last being referred from foster homes. Parents of 43 were chronic alcoholics, parents of 43 were openly hostile, and those of 28 were oversolicitous. A striking fact is that only 17 patients had other siblings who were behavior problems.

The problems that led to admission were many. Forty six were admitted for stealing, 33 for sexual

puberty; therefore, our groups were built around this age range. Four groups were chosen: four to nine as the childhood period; ten to twelve as the preadolescent period; thirteen to fifteen as the early adolescent period, and sixteen to eighteen as the late adolescent period. Figure 1 shows the distribution of patients and controls.

Since we were dealing with an age range in which the normal electroencephalogram differs from the adult pattern and varies from year to year in its development into the adult pattern (Smith,<sup>3</sup> Lindsley<sup>2</sup> and Gibbs and Gibbs<sup>8</sup>), we obtained tracings on 76 control children (69 boys and 7 girls) of the same age range as the group

FIGURE 2 Samples of Normal, Immature Borderline and Immature Abnormal Electroencephalographic Tracings

Most of the samples were taken from the older age groups. Some of the samples in the immature borderline group, for example, the second one, would be considered normal in a child of six or seven. The vertical lines through the tracings represent 50 microvolts. It should be noted that the degree of amplification varies in the different tracings.

misbehavior, 32 for being runaways and 21 for temper tantrums; 15 were called "stubborn children" by the courts, 13 were truants, 9 set fires and 5 were depressed. A number of children had more than one type of undesirable behavior.

All the children adjusted themselves well on the wards and gave no evidence of being behavior problems, except for 21 who were overactive, sulky, vindictive, noisy or destructive, or had temper tantrums when verbally reproached.

Since a study of juvenile delinquency by the Gluecks<sup>7</sup> stressed the fact that delinquency decreases with increase in maturity, it seemed advisable to divide the cases into age groups. The majority of patients were between the ages of thirteen and fifteen. This age range is a particularly vulnerable period, owing to the onset of

of behavior problem children. They were selected from a middle class population, and to the best of our knowledge, they were from good homes and environment and were not recognized as presenting any problem at home, in school or in the community. Intelligence quotients were not available, but we estimate that the children were at least of average intelligence.

#### APPARATUS AND PROCEDURE

The records were obtained with a Grass six-channel electroencephalographic apparatus. Electrodes were placed over the frontal, precentral and occipital regions of each hemisphere, the indifferent electrode being placed over the mastoid. Two types of records were obtained: six simultaneous recordings from each of the frontal, pre-

central and occipital areas of the two hemispheres, grounded to the indifferent mastoid electrode; and six simultaneous bipolar records, including the left frontal to left precentral, right frontal to right precentral, left precentral to right precentral, left precentral to left occipital, right precentral to right occipital, and left occipital to right occipital. The records were obtained with the patient lying down and with the eyes closed. Hyperventilation for a period of two minutes was done in all the controls and in most of the patients.

#### ANALYSIS OF RECORDS

The tracings are divided into three groups: normal, immature-borderline and immature-abnor-

FIGURE 3. Percentage Distribution of Normal, Immature-Borderline and Immature-Abnormal Electroencephalographic Tracings from Patients and Controls.

*Normal tracings are much less common in the behavior-disorder group.*

mal (Fig. 2). Because of the normal immaturity of the pattern in childhood and early adolescence, it is impossible to say whether an atypical pattern at a given age represents a delay in the maturity of the pattern or whether it is secondary to some congenital or acquired injury to the brain. It would be incorrect to label a patient's brain waves as abnormal when the unusual activity might be due only to a delay in his maturity. Consequently, when patterns are not normal for a given age, we prefer to consider them either immature-borderline or immature-abnormal, depending on the degree to which they deviate from the normal

pattern of that age range. The evaluation of hyperventilation in children is complicated by the fact that normally the brain potentials are more vulnerable to this procedure than those of adults. This vulnerability decreases with increase in age. We have used our controls as a guide in evaluating the response to hyperventilation in the patients.

Recently, Davis and Wallace<sup>9</sup> have demonstrated that brain potentials in normal persons who tend to run low blood-sugar levels or who have not eaten for several hours are vulnerable to hyperventilation. Since all our control records were obtained at five o'clock in the evening (four to five hours after lunch time), whereas most of the patients' records were obtained between one and two o'clock (one or two hours after lunch time), our controls were overweighted, so far as anomalies of hyperventilation, resulting from a low blood sugar, are concerned.

#### RESULTS

Of 143 children presenting behavior disorders, 26 per cent had normal, 23 per cent borderline and 51 per cent abnormal electroencephalograms; whereas of the 76 controls, 68 had normal, 17 had borderline and 15 per cent abnormal tracings (Fig. 3). As a group, the electroencephalograms of the behavior disorders were more vulnerable to hyperventilation than those of the controls (Table 1). This finding is in agreement with the conclusions of Lindsley and Cutts.<sup>6</sup>

The controls and the patients were divided into age groups; and the percentages of normal, im-

mature-borderline, and immature-abnormal records that occurred in each age group were compared. Moreover, when one compared age group with age group, there was, on the whole, a progressive increase in normal records and a diminution in abnormal records with increase in age (Fig. 4). There was no significant difference in the percentage of behavior-disorder children with abnormal records who were adjusted on the ward and those who continued to exhibit maladaptation.

Twenty-four (16 per cent) of the children with behavior disorders had inferior intelligence; and of these, 15 (62 per cent) had abnormal tracings. Of the 119 who had normal intelligence, 59 (50 per cent) had abnormal tracings. This is not a significant difference.

## DISCUSSION

This study demonstrates that the electrocerebral activity of many children with behavior disorders is not normal. A wave of slow rate is the commonest abnormal finding in these patterns. In the adult, such a wave is definitely abnormal, but in early childhood slow activity is a normal finding; therefore, a greater degree of slow activity than

to adjust themselves better with minor alterations in environmental stresses under proper psychiatric guidance. On the other hand, an abnormal tracing in such children indicates a degree of cerebral immaturity incommensurate with the chronological age reached, and therefore a child less likely to respond to minor variations in his milieu. An effort should immediately be made to place him in

FIGURE 4. Percentage Distribution of Normal, Immature-Borderline and Immature-Abnormal Electroencephalographic Tracings (Patients and Controls) in Each Age Group.

*There is a greater percentage of abnormal tracings in the behavior disorders in each group than in the controls. The diagram also illustrates that with increase in age there is a diminution in the percentage of immature-abnormal tracings in the children with behavior disorders.*

is consistent for a normal record of that age range may be due to a delay in the normal development of the cerebrum. A further evidence of immaturity in these cases was the frequent occurrence of neurotic traits, such as enuresis, thumb sucking and nail biting. The tracing is a measure of the delayed development of the cerebrum; because of this delay in development, these patients do not make a satisfactory adjustment either to their environment or to the impact of puberty—46 per cent of the cases were between the ages of thirteen and fifteen. The fact that only 17 patients had siblings who were behavior problems, although subjected to the same environment, suggests that the environment is only a precipitating factor.

We believe that the electroencephalograph may become a useful adjunct in guiding therapeutic approach. For example, behavior-problem children with normal tracings might be expected

an environment modified to suit his limitations until he has achieved sufficient maturity.

## SUMMARY

The electroencephalograms of 143 children presenting behavior disorders are compared with those of a group of 76 normal controls of the same age range. The former had a higher percentage of immature-abnormal tracings and were more vulnerable to hyperventilation than the latter.

The patients and controls were divided into age groups: four to nine, ten to twelve, thirteen to fifteen and sixteen to eighteen. The patients with behavior disorders in each age group had a higher percentage of immature-abnormal tracings than the controls. Moreover, the records of the behavior disorders, comparing age group with age group, showed a progressive increase in normal records and a diminution in immature-abnormal records

with increase in age (from 74 per cent in the group from four to nine to 34 per cent in that from sixteen to eighteen). The possibility that the decrease in immature-abnormal records in the older age group was related to the maturation of the cerebrum is discussed.

## MEDICAL PROGRESS

### ARTIFICIAL RADIOACTIVE ISOTOPES IN MEDICINE AND BIOLOGY\*

JOSEPH F. ROSS, M.D.†

BOSTON

THE application of the isotopic tracer technique to medical investigation ranks in importance with the invention of the microscope and the discovery of the x-ray. During the relatively few years that isotopes have been employed in biologic research, they have contributed to fundamental discoveries in intermediary metabolism, and have provided new and promising forms of therapy for otherwise hopeless diseases.

The chief and unique value of isotopic tracers lies in their applicability to the study of normal metabolic processes in undisturbed organisms in functional, nutritional and energetic equilibrium. Previous methods of metabolic study, which relied on chemical technics, were of necessity concerned with the determination of accumulations of unnatural intermediate or end products, and frequently utilized observations made on sick or deranged organisms. However, with the use of isotopic tracers, the ebb and flow and interchange of normal foodstuffs, intermediate metabolic products, vitamins and even hormones can be followed in intact, living organisms.

Briefly, isotopes are atoms with identical chemical and biologic properties (since their nuclear charges and atomic numbers are the same), and are distinguished only by differences in atomic weight. Some isotopes are stable,—that is, they never change,—whereas others are radioactive and sooner or later undergo nuclear changes with the emission of radiations (gamma rays, beta rays or alpha particles). The stable isotopes, because of

the differences in their atomic weights, can be separated and detected quantitatively with the mass spectrometer, and the radioactive isotopes can be followed with an electroscope or a Geiger-Müller counter (instruments capable of detecting radiations). Since the organism does not distinguish between labeled and ordinary isotopes of the same element, biologic reactions in which the tracer isotope participates are identical with those occurring simultaneously with ordinary isotopes.<sup>1-3</sup> By the use of appropriate technics of detection, both stable and radioactive isotopes can therefore be employed in biologic research as marked or labeled atoms that serve to indicate the paths and reactions of their ordinary fellow atoms. It must be emphasized that the atoms of radioactive isotopes, except for slight differences in atomic weight, are indistinguishable from other atoms of the same element until they instantaneously give off their radiation. The amounts of radiation liberated by the minute "tracer doses" employed in biologic investigations are so small that they produce no alteration in normal physiologic processes, and it is only when large "therapeutic doses" are administered that radiation effects are produced.

The application of the isotopic tracer technique to biology is actually very simple. A substance—for example, an amino acid or a simple inorganic compound such as sodium phosphate—containing either stable or radioactive tracer atoms is fed to an animal or human subject, and subsequently the blood, tissues or secretions are tested for the presence of the labeled atoms. The presence of such atoms in any particular tissue indicates that some of the ingested material has been deposited in that tissue. In this fashion, the fate of the particular molecules of the amino acid or sodium phosphat

Reprints of articles in this series are not available for distribution, but the articles will be published in book form. The current volume is *Medical Progress: Annual, 1940* (Springfield, Illinois: Charles C Thomas Company, 1941. \$4.00).

†Instructor in medicine, Boston University School of Medicine; associate, Robert Dawson Evans Memorial, Massachusetts Memorial Hospitals.

that were fed to the experimental subject can be distinguished from the fate of similar but unlabeled molecules of amino acid or sodium phosphate already present in the body. For example, by injecting sodium bicarbonate labeled with radioactive carbon and subsequently demonstrating the presence of this radioactive carbon in glycogen from the liver, Conant and his associates<sup>4</sup> were able to show that the animal organism can utilize carbon dioxide for the synthesis of glycogen. This truly revolutionary discovery could have been accomplished only by the use of a technic that allowed distinction between carbon atoms in the injected sodium bicarbonate and the carbon atoms of the complex carbohydrates already present in the body.

As early as 1923, Hevesy,<sup>5</sup> using the naturally occurring radioactive isotope of lead (radium D), studied the circulation of lead in plants, and similar technics were later applied to bismuth. Naturally occurring radioactive isotopes are few in number, however, and therefore the radioactive tracer technic could not be extensively applied to biologic investigation. The discovery by Joliot and Curie<sup>6</sup> that atoms could be made radioactive by artificial means, and the invention and development of the cyclotron by Lawrence and Cooksey,<sup>7</sup> made possible the production of artificially radioactive isotopes of practically all the elements, and during the last six years, many of these radioactive substances have been employed in biologic investigation. As medical investigators become familiar with the possibilities of this technic, and as more strongly radioactive substances are prepared and the methods of detection are made more sensitive, the use of isotopic tracers will undoubtedly be greatly expanded and will allow approach to many problems hitherto impossible of solution.

Although the only essential difference between the stable and radioactive isotopic tracer technics lies in the method of detection, this report is limited to a discussion of the radioactive tracers. An excellent review of the biologic applications of the stable isotopes has recently been prepared by Schoenheimer and Rittenberg.<sup>8</sup>

The extensive applications of radioactive tracers to studies of plant<sup>9</sup> and insect<sup>10</sup> physiology are beyond the scope of this paper, which is intended primarily to summarize only the more significant contributions with direct bearing on medical science.

Complete reviews of radioactive technics and of their varied applications have been prepared by Evans,<sup>11</sup> Greenberg,<sup>12</sup> Hamilton,<sup>13</sup> Hevesy<sup>14</sup> and Lawrence.<sup>15</sup>

## PHOSPHORUS

Radioactive phosphorus was the first of the isotopes to be applied to investigations of animal metabolism, and was used by Hevesy and his associates<sup>14, 16</sup> to study the absorption and distribution of phosphorus in rats, and to trace the formation of phospholipids and other phosphorus-containing organic substances in various tissues. During the seven years since this work was reported, over a hundred papers have appeared dealing with the application of this technic to studies of phosphorus metabolism. It was found that inorganic phosphates were readily absorbed from the upper intestinal canal, and were quickly converted into organic phosphorus compounds.<sup>17-19</sup> Phospholipids were synthesized most rapidly in the liver, kidney and intestinal wall and more slowly in other organs and tissues.<sup>20</sup> Phospholipid synthesis was apparently carried on in each tissue independently of similar activity in other organs,<sup>21</sup> and continued in tissue slices *in vitro*.<sup>22</sup> The rate of phospholipid turnover was definitely influenced by the level of lipids in the circulating blood, being accelerated when fats were absorbed from the intestine.<sup>21</sup>

Various footstuffs greatly influence the deposition of fat in the liver, and considerable interest has arisen concerning the role that these substances play in preventing or producing liver disease. The mode of action of such substances has been studied with the use of radioactive phosphorus as an indicator of phospholipid formation. It was found that the increase in liver fat produced by the feeding of cholesterol was associated with a decrease in the rate of formation of new phospholipid, although the total phospholipid content of the liver was not changed.<sup>23</sup> Choline, cystine and methionine (lipotropic substances) produced an opposite effect,—that is, a decrease in total liver fat and an acceleration in turnover of phospholipid,<sup>24-26</sup>—whereas other amino acids had no such effect.<sup>27</sup> It thus appears that the substances controlling deposition of lipids in the liver exert their effect by influencing phospholipid turnover.

The major portion of any given dose of radioactive phosphorus is eventually deposited in the bones.<sup>28, 29</sup> Therefore, the structures in close proximity to bone, such as the marrow, are subjected to localized bombardment by the beta rays given off by the decaying isotope. The first observations of the effect of such radiation were made by Scott and Cook,<sup>30</sup> who fed large doses of radioactive phosphorus to chicks and found a subsequent decrease in the number of circulating leukocytes. This observation suggested that radioactive phosphorus might be a valuable therapeutic agent in diseases in which there was abnormal

growth of leukocytes, such as leukemia. Lawrence and Scott<sup>31</sup> and Lawrence, Tuttle, Scott and Connor<sup>32</sup> investigated the effect of radioactive phosphorus on mice with leukemia, and found that it decreased the number of abnormal leukocytes in the circulating blood, and that the uptake of radioactive material by leukemic lymph nodes and spleens was three times greater than the uptake by normal lymph nodes and spleens. Subsequent studies showed that the rapid assimilation of radioactive phosphorus by tumor tissue was merely a reflection of its rapid metabolism, and was not a peculiarity of the tumor tissue itself.<sup>33-40</sup> However, the concentration of the radioactive material in neoplastic tissue subjected it to localized, *in situ* radiation, with resultant selective destruction of tumor cells, and explained the beneficial effect of radioactive phosphorus on animals with experimental leukemia.

These findings led to the therapeutic administration of radioactive phosphorus to human beings with leukemia, and in general the results were similar to those observed in animals with experimental leukemia. Patients with leukemia and polycythemia retained more radioactive phosphorus than normal persons, and it was concentrated in tumor tissues, leukemic leukocytes and leukemic bone marrow,<sup>41-43</sup> where it was built into nucleoproteins and phospholipids.<sup>39, 40</sup> The leukemic cells in the bone marrow, lymph nodes and peripheral blood were thus subjected to fairly specifically localized and intense radiation.

Erf, Tuttle and Lawrence,<sup>44</sup> who have recently summarized their clinical experiences with radioactive phosphorus in 100 cases of leukemia, believe that this form of therapy has distinct advantages over x-radiation because of the ease with which it can be administered (either by mouth or by intravenous injection), and because of the freedom from subsequent radiation sickness and skin reactions. They observed no clinical improvement in the patients with acute leukemia who were treated, although Warren<sup>45</sup> reported definite improvement in certain patients with acute leukemia treated with intravenously administered radioactive phosphorus. The results in chronic leukemia were more encouraging<sup>44</sup>: of 63 patients treated with radioactive phosphorus, 19 showed clinical improvement lasting from three to twelve months, 6 were completely well with normal laboratory findings for periods ranging from three months to two and a half years, and 2 were apparently completely cured and still living after two years. Investigators<sup>46</sup> at the Memorial Hospital in New York also found radioactive phosphorus a good and reliable therapeutic agent for lymphosarcoma and for chronic myelogenous and lymphatic leukemia, although it proved of little benefit in acute leukemia and in various other neoplastic diseases.

The natural history of leukemia, with its frequent remissions and exacerbations, necessitates extreme caution in evaluating the results obtained from any form of therapy, and since radioactive phosphorus has been used extensively for the treatment of leukemia for only two years, it is hazardous to draw too sweeping conclusions regarding its actual advantage over other forms of radiation therapy. Careful review of the reported cases indicates that the end results were little different from those that would have been obtained with x-radiation.

Six patients with polycythemia vera have been treated with radioactive phosphorus.<sup>47</sup> Considerable clinical improvement was noted, and there was some reduction in the erythrocyte count and hemoglobin level. The benefits obtained do not appear to have been superior to those that could have been achieved with the much less expensive and simpler procedures of restricting iron intake and performing phlebotomies.

All in all, radioactive phosphorus therapy appears to be a convenient but expensive method of administering radiation therapy to patients with leukemia and polycythemia. The results obtained are at least as good as those to be expected from x-ray treatment, and the technic definitely merits further investigation.

### IRON

For many years, there has been considerable controversy concerning the absorption and excretion of iron, and the most favorable form of the element for therapeutic use. Since it was impossible chemically to distinguish between iron that passed through the intestinal canal unabsorbed and iron that might have been excreted into the intestine, some investigators claimed that large quantities were absorbed and re-excreted, whereas others found that absorption did not take place in normal persons. With the use of radioactive iron, this problem has been solved, since the exact fate of a particular dose of iron can be determined accurately. Hahn and his collaborators<sup>48</sup> applied the radioactive tracer technic to the study of iron metabolism in dogs, and found that normal and plethoric animals absorbed very little iron, and that anemic animals assimilated considerable quantities. Moreover, iron absorption was controlled by the state of iron reserves in the body and not by the anemia *per se*, since animals made acutely anemic absorbed no more iron than they did when their blood levels were normal, and it was only after depletion of the iron stores in the tissues that iron was taken up from the bowel.<sup>49</sup>

Ross and Chapin<sup>50</sup> found that normal human subjects absorbed very small amounts of iron, although patients with the hypochromic anemia of

iron deficiency took up much larger amounts. Patients with untreated pernicious anemia, a condition in which the iron reserves of the body are adequate in spite of marked anemia, absorbed no more iron than normal subjects. However, the same patients took up considerable quantities of iron after treatment with liver extract and after depletion of body reserves of iron, even though the anemia had been relieved and was of minimal degree. The ferric, ferrous and reduced forms of iron were absorbed and utilized for hemoglobin formation with equal rapidity and facility.<sup>51, 52</sup> Insignificant amounts of iron were excreted in the urine and bile, and only minute amounts were eliminated in the feces under normal conditions, several years being required to excrete a surplus of iron equivalent to the total iron content of circulating hemoglobin.<sup>53</sup> These studies indicate that human subjects and experimental animals control iron metabolism by regulating the amounts of iron absorbed and not, as was formerly believed, by varying the amount excreted. In some way as yet unexplained, iron absorption occurs only when the reserves of tissue iron are depleted.

After absorption, radioactive iron is incorporated into the hemoglobin molecule with extreme rapidity, and is released into the circulation in newly formed erythrocytes within a few hours after ingestion.<sup>51, 54</sup> Once built into the hemoglobin molecule, radioactive iron is "fixed" within the erythrocytes,<sup>55</sup> and has provided a new method for studying cell and blood volume, since the total volume of blood or cells can be calculated from the degree of dilution of a known number of tagged cells injected into the vascular system of experimental subjects. With the use of cells labeled in this way, it has been found that the total volume of cells in the vascular system is less than was formerly supposed, and that very few if any cells are immobilized in the spleen or elsewhere in the body.<sup>56, 57</sup> The concept that the spleen serves as a reservoir for erythrocytes that can be mobilized in times of stress is thus subjected to serious doubt, and the increase in hematocrit produced by administration of adrenalin is probably caused by a redistribution of cells and plasma in the vascular system.

Further application of the radioactive tracer technic should clarify many problems of hemoglobin and iron metabolism, and the use of erythrocytes tagged with radioactive iron may be of considerable value in studying the changes in blood volume that occur in shock, cardiac failure and pregnancy.

#### IODINE

By means of radioactive iodine, it has been possible to follow the uptake of iodine by the thyroid gland, and to detect differences in iodine

metabolism in various types of thyroid disease.<sup>58</sup> When a suitably designed radiation detector was placed over the thyroid gland, and the patient then fed radioactive iodine, the rate of deposition of the radioactive material in the thyroid was registered on the counter. Normal subjects took up an amount of iodine approximately equivalent to that already present in the gland, and a maximum concentration was reached in about two days. This concentration was then maintained at a fairly constant level for the ensuing thirty days. In marked contrast to the normal glands, hyperactive glands of patients with Graves's disease assimilated four or five times more iodine, and took it up at an extremely rapid rate, the maximum concentration being reached in approximately four hours. The rapid uptake was followed by a rapid loss of iodine during the next few hours; this fact indicated that the mechanism by which the hyperactive gland stored iodine was much different from that of normal glands. Nontoxic goiters took up larger quantities of iodine than normal glands, but the rates of uptake and storage were very similar; iodine metabolism in nontoxic goiter was accordingly not significantly different from that of the normal gland. Atrophic glands of patients with myxedema took up only very minute quantities of iodine. Very recently, Hertz and Roberts<sup>59</sup> have employed the differential rates of iodine uptake by thyroid glands to distinguish between two types of hyperthyroidism that they classify as "ophthalmopathic" and "classic" Graves's disease.

Pretreatment with iodine markedly decreased the subsequent uptake of iodine by both normal and hyperactive glands.<sup>60-62</sup> This information has been applied clinically with the discovery that a single large dose of iodine produces the same therapeutic effect in Graves's disease as repeated massive iodination.<sup>61</sup> This suggests that the common clinical practice of administering Lugol's solution to patients with Graves's disease for weeks prior to thyroidectomy is unnecessary, a single large dose probably being about as effective.

The exact sites of localization of iodine in thyroid tissue can be determined by the unique technic of "radio autography." When thin sections of thyroid tissue containing radioactive iodine (removed from patients previously fed radioactive iodine) are placed on sensitive photographic plates, the beta rays liberated by the iodine expose the plate, the heaviest exposure being produced in regions in which the radioactive iodine is most concentrated. If these tissue sections are then stained and examined histologically, the areas of exposure on the photographic plate can be identified with the corresponding areas in the tissue, and the exact site of localization of the iodine easily determined.<sup>63</sup> Such studies show that iodine

is deposited in equal concentrations in the colloid and cells of active glands. However, carcinomatous thyroid tissue does not take up iodine. It is thus impossible to administer therapeutic radiation to this neoplastic tissue *in situ*, in the way that radiation can be given to leukemic tissue with radioactive phosphorus. On the other hand, since radioactive iodine does localize in hyperplastic thyroid tissue, Hertz and his associates<sup>60</sup> are employing radioactive iodine therapeutically in patients with Graves's disease. Considerable amounts of radiation can be administered *in situ* in this way, and it is hoped that this radiation will serve to inhibit the overactivity of the parenchymal cells, and thus reduce the overproduction of thyroid hormone.

#### SODIUM AND POTASSIUM

Radioactive sodium and potassium have been used extensively in the study of the permeability of various cell membranes to cations, and the essential extracellular nature of sodium and the intracellular character of potassium have been verified. Radioactive sodium entered the intracellular phase of sodium-containing tissues in proportion to the sodium content of the tissue—an indication that the cell membranes of such tissues are not completely impermeable to sodium.<sup>64</sup> Erythrocytes are permeable to both potassium and sodium ions,<sup>64-68</sup> and the classic theory of cation impermeability of the erythrocyte must therefore be considered as relative only. The cell membrane is undoubtedly more permeable to anions than it is to cations, but cations do penetrate it, and the difference in concentrations of cations inside and outside the cell must be due to some mechanism other than mere membrane impermeability.

Zwaardemaker<sup>69</sup> advanced the theory that the physiologic activity of some elements might be due to their natural radioactivity, and suggested that the intrinsic rhythmicity of the heart beat might be caused by the radiations given off by the naturally occurring isotope of potassium. He believed that the cessation of the heart beat produced by removal of potassium from perfusing fluid was due to the removal of these radiations. Glazko and Greenberg<sup>70</sup> effectively disproved this theory by replacing the potassium of perfusing fluid with radioactive sodium, which supplied infinitely more radiations than the naturally occurring radioactive potassium but which did not maintain cardiac rhythmicity. Various radioactive substances produced no immediate physiologic changes, even when the amount of radioactivity administered was very large.<sup>71</sup>

The possibility that neoplastic disease is caused by the concentration of naturally occurring radioactive potassium in tissue has been investigated by Lasnitzki,<sup>72</sup> who found that radioactive potassium was present in identical concentration in all

tissues studied, both normal and neoplastic. The same investigator<sup>73</sup> has recently reported, however, that the light, stable isotope of potassium ( $K^{39}$ ) is concentrated in tumor tissue, and in normal muscle tissue of tumor-bearing animals.

Since sodium is essentially extracellular in distribution, a method of determining extracellular fluid volume with radioactive sodium has been developed.<sup>74</sup> By this procedure, the average extracellular volume of human subjects was found to be 17.7 liters, or 23.5 per cent of the body volume. Approximately 85 per cent of this fluid was extravascular, and 15 per cent intravascular. Because of technical difficulties, this method is not so practical as the simpler thiocyanate one in general use.

#### CALCIUM AND STRONTIUM

Calcium and strontium are members of the same group in the periodic table of elements, and Pecher<sup>75, 76</sup> has found that radioactive calcium and radioactive strontium are distributed and metabolized in the animal organism in a similar fashion. Both are deposited in the skeleton, particularly in trabecular bone, epiphyses and regions of active skeletal growth.<sup>77</sup> The beta rays given off by radioactive calcium are too weak to be of value therapeutically, but the energetic beta particles emitted by radioactive strontium are capable of producing considerable tissue ionization, and should be of definite value in destroying neoplastic tissue. Consequently, since radioactive strontium is deposited in the newly formed osseous tissue of bone tumors, it is being used in the treatment of osteogenic sarcoma with the hope that radiation liberated *in situ* will be more effective than external x-radiation.<sup>75</sup>

#### CARBON

The carbon dioxide formed by the metabolism of the animal organism has been considered a waste product, and the animal organism was believed to be entirely dependent on the plant kingdom for conversion of inorganic carbon to organic forms suitable for foodstuffs. The recent work of Conant, Hastings and their associates<sup>4, 78</sup> indicates that this concept must be revised, and that the animal organism can use inorganic carbon dioxide for the formation of carbohydrates. Lactic acid containing radioactive carbon was fed to starved rats, and after two and a half hours, glycogen was isolated from the liver and assayed for its content of radioactive carbon. Although the amount of glycogen formed corresponded to 30 per cent of the lactate administered, only 1.6 per cent of the administered radioactive carbon was found in this newly formed glycogen; this indicates that the carbon used for synthesizing this glycogen did not originate directly or solely from the lactic acid molecule. This carbon must therefore have been

derived from some endogenous source, probably carbon dioxide. Subsequently, by injection of sodium bicarbonate containing radioactive carbon into starved rats, it was found that considerable amounts of the labeled carbon from the bicarbonate had been deposited in the liver as glycogen. It thus appears that the carbon dioxide liberated by carbohydrate catabolism is not entirely a waste product, but can be reutilized in the liver for formation of new glycogen.

### SULFUR

Sulfur compounds play a very significant role in numerous oxidation-reduction reactions in the body, and the essential nature of methionine, cystine and thiamin is well established. However, the intermediary metabolic reactions of these substances and their eventual fate in the body are still obscure. Using radioactive sulfur as a label, several investigators have studied the reactions of these substances in the body. Ingested inorganic sulfur apparently exchanged with the sulfur of the tissues to some extent, since its complete excretion was delayed.<sup>79</sup> It was not incorporated into cystine, however, and the sulfur of cystine did not exchange with inorganic sulfur.<sup>80, 81</sup> Thiamin (vitamin B<sub>1</sub>) containing radioactive sulfur was rapidly destroyed by both normal and thiamin-deficient human subjects.<sup>81</sup> Approximately 10 per cent of the body's content of vitamin B<sub>1</sub> was broken down every twenty-four hours.<sup>83</sup> When thiamin was injected into subjects maintained on a normal diet, there was a very large wastage, 61 per cent appearing in the urine and 11 per cent in the feces within a few hours.<sup>82, 83</sup> These findings indicate the probable futility of attempting to increase the body's stores of thiamin above the normal level.

### COBALT, COPPER, MANGANESE AND ZINC

Minute amounts of cobalt, copper, manganese and zinc are essential for the normal health and nutrition of animal organisms, but little is known of the exact roles that they play in metabolic processes. The radioactive isotopes of all these elements are easily prepared and detected, and afford an entirely new method of investigating their biologic activities. At present, they have been employed only for the study of absorption and excretion in animals,<sup>84-86</sup> but it is probable that they may soon be used in investigations of various essential enzyme systems.

### ARSENIC

Arsenical compounds are valuable therapeutic agents in syphilis and in various parasitic infections, although little is known of their distribution or mode of action. With the intention of

termining their action in these diseases, several investigators<sup>87, 88</sup> have made careful preliminary studies of the distribution of such compounds in various animals. Soon after injection, arsenic is concentrated in the liver, kidneys and lungs, but subsequently is so rapidly excreted in the urine that only minute amounts remain in the body after one week.

\* \* \*

Radioactive isotopes have been employed extensively as indicators of metabolic activity in experimental animals, and have been of greatest value in elucidating fundamental problems of normal physiology. The isotopic tracer technic has been applied to the study of disease in human beings only during the last three or four years, but already has resulted in significant improvement in the therapy of several metabolic and neoplastic diseases. Extension of the technic to other diseases will undoubtedly lead to a better understanding of underlying pathologic physiology and indicate new and better forms of treatment.

ANTE-MORTEM AND POST-MORTEM RECORDS AS USED  
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

CASE 28211

## PRESENTATION OF CASE

A sixty-three-year-old businessman was admitted to the hospital because of fever, cough, chest pain and sputum.

The patient had been in fair health except for "arthritis," some malnutrition and a chronic cough that was productive of about a cupful of sputum a day during the six months before entry. Two days before entry, following exposure to cold, he experienced a shaking chill followed by fever and pain in the front of the left chest; this was made worse by breathing. The sputum became tinged with blood.

The patient drank much alcohol until four years before entry and ate very poorly. The more remote history was not available.

Examination showed an acutely ill man, flushed and dyspneic with dusky cyanosis. There was dullness in the left midaxilla extending to the left base posteriorly, where breath sounds were diminished, with a suggestion of bronchovesicular breathing and rhonchi. There was a questionable friction rub. The heart seemed normal. The abdomen was very slightly distended.

The blood pressure was 130 systolic, 80 diastolic. The temperature was 99.5°F., the pulse 112, and the respirations 31.

Examination of the blood showed a red-cell count of 3,620,000 with 11.3 gm. hemoglobin, and a white-cell count of 18,000 with 90 per cent polymorphonuclears, 7 per cent lymphocytes and 3 per cent monocytes. The blood Hinton reaction was negative. The urine showed a +++ test for albumin, a specific gravity of 1.010 and a sediment containing numerous white blood cells with rare casts and red cells and no bacteria. A Type 9 pneumococcus was identified in the sputum by the Neufeld reaction.

Röntgenograms of the chest showed generalized increase in linear markings throughout the right lung field and in the upper portion of the left lung field. The lower part of the left lung field was homogeneously dense, and in the lateral view showed numerous areas of consolidation in the region of the left lower lobe. There was much calcification in the aorta.

The patient was treated with small doses of sulfadiazine and did fairly well for two days. The

temperature ranged from 98.6 to 100°F. The urine remained filled with white blood cells and albumin. On the third hospital day, there was gross hematuria, and the patient complained of pain in the left flank. No crystals were evident in the urine, and the sulfadiazine blood level had reached a maximum value of only 8 mg. per 100 cc. The nonprotein nitrogen was 56 mg. per 100 cc., rising to 75 mg. two days later. Intravenous glucose in physiologic saline solution was given in four clyses. On the fifth hospital day, there was complete dullness over the left lower lobe, with diminished breath sounds. The next day, extreme dyspnea appeared. The temperature spiked to 102°F. for one reading. Bubbling rales became audible in both lung fields. On the eighth day, the patient became cyanotic, and the systolic blood pressure dropped to about 100. The urinary output became less than 500 cc. per day, with a specific gravity of 1.006, a + test for albumin and many red cells and a few unidentified crystals in the sediment. The nonprotein nitrogen rose to 102 mg. per 100 cc. Cheyne-Stokes respirations appeared, and the patient expired the following day.

## DIFFERENTIAL DIAGNOSIS

DR. JOHN H. TALBOTT: This patient had an exudative respiratory disturbance for six months and an acute respiratory disease for two days. We have no further information about the "arthritis," the anemia or the cause of the malnutrition. He had been a heavy imbibor of alcoholic beverages. These facts are probably incidental to the malady responsible for death. The association of arthritis and kidney disease makes one raise the question of gout, but I think we can dismiss it without further consideration. There is no evidence that the patient had cirrhosis of the liver, which one might suspect on the basis of the alcoholic history. There are no data about urinary symptoms or other evidence to suggest a nephritis. The first evidence of kidney disease was observed on admission to the hospital; this was in addition to an acute pulmonary process. Nothing is stated about the examination of the fundi. We do not know whether there were any retinal changes, which are most important diagnostically in a consideration of a kidney lesion. I realize that a patient who comes in with pneumonia may have a very cursory examination of the eyegrounds. Was any statement made in the record about a retinitis?

DR. TRACY B. MALLORY: There is a check against "fundus" on the chart, which should mean that they were looked at and nothing found.

DR. TALBOTT: The patient had clinical signs of pneumonia and a white-cell count of 18,000. The

temperature was 99.5°F., the pulse 112, and the respirations 31.

I should like to see the x-ray films.

DR. MALLORY: The films were lost.

DR. TALBOTT: I was afraid something like that would happen, having hoped that we should get additional information, from the interpretation of the x-ray films, whether or not there was pulmonary edema such as might be seen in acute nephritis.

We must be content with what we are given in the record. The absence of clubbing of the fingers makes one disinclined to attribute too much significance to the chronic cough, such as might be associated with bronchiectasis or advanced pulmonary fibrosis. Undoubtedly, this patient had a chronic pulmonary process as well as an acute one. There was no history of exposure to tuberculosis, no examination of the sputum for tubercle bacilli, and no history of hemoptysis. I am inclined to make a diagnosis of chronic nontuberculous pulmonary infection, which was probably exaggerated by bronchitis in the six months before admission and was responsible for the expectoration of a cupful of sputum daily. The acute process was probably a pneumococcal pneumonia.

DR. MALLORY: The X-ray Department did call it pneumonia.

DR. TALBOTT: Now we come to the kidneys. It is stated that the patient had small doses of sulfadiazine, and yet the blood level rose to 8 mg. I think one can say that some renal impairment must have existed to give a blood level of 8 mg. on small doses of sulfadiazine. The onset of pain in the left flank, followed by hematuria and a rising nonprotein nitrogen, makes me believe that this patient had renal impairment secondary to sulfadiazine toxicity. Renal involvement following sulfadiazine ingestion is not so common as it is with some of the other sulfonamides. Two conditions may predispose to the development of a sulfadiazine reaction in the kidney: a patient may develop a sensitivity to the drug because of previous ingestion; and probably much more important clinically is the presence of a pre-existing renal disease. A patient who has a pre-existing renal disease is more prone to develop renal toxicity from any of the sulfonamides. The acute episode on the second day was, I believe, associated with sulfadiazine damage to the kidney, and I think we are going to find, if the kidney was prepared properly, plenty of evidence of sulfadiazine crystals microscopically.

So far as the mechanism of renal damage from sulfonamides is concerned, it is probably a combination of toxic damage to the parenchyma of

the kidney and plugging of the convoluted tubules by precipitated crystals. Patients who develop a sulfonamide reaction may have complete shutdown of one or both kidneys. The sulfadiazine reaction was treated with intravenous glucose and physiologic saline solution. I have no comments to make in this connection. I think the use of saline is undesirable in sulfonamide anuria. The solubility of sulfonamides is depressed in a urine of high salt content. If urination is resumed, the tendency to further precipitation is augmented. Moreover, intravenous saline solution may cause some edema of the tubules and delay restoration of function. I think a patient with a sulfadiazine reaction should probably get glucose and not saline solution. The question of alkalinity of body fluids, particularly urine, has been raised in connection with sulfadiazine reactions in the kidney. There is conflicting evidence in the literature concerning whether or not an alkaline urine is less harmful to a damaged kidney than an acid one. Indian evidence is based on renal damage from transfusion, in which the precipitation of hemoglobin or rather the damage from precipitation of hemoglobin, is less with an alkaline than with an acid urine. On the basis of this and other experimental evidence, I should have recommended either sodium bicarbonate by mouth or sodium lactate intravenously and continued alkalinization of the patient until most of the evidence of kidney damage had disappeared.

What is the prognosis in renal toxicity due to sulfadiazine? This patient died. If he had had an overwhelming malady, I do not believe that the kidney damage itself would have been fatal. Did he die of pneumonia alone? I do not believe so. I think it was a combination of renal disease and pneumonia. The renal disease was also a combination of sulfadiazine reaction superimposed on the pre-existing kidney disturbance.

What was the nature of this kidney disturbance which was manifested by a ++++ test for albumin on admission and a + test for albumin on one or two subsequent occasions? The patient had a specific gravity of 1.010 on admission; yet presumably was dehydrated. One can assume that any patient who has pneumonia is probably dehydrated by the time he comes to the hospital. The sediment contained many white cells, but red cells were noted until after the ingestion of sulfadiazine.

Was this an acute or a chronic nephritis? If it were the former, it might be associated with bronchitis. We have no evidence—from the physical grounds, from the blood pressure or from the history of kidney disease—whether or not

thing had been going on in the kidney before admission to the hospital. I do not believe I can go any farther in differentiating the primary renal lesions in this patient beyond affirming that there was something that predisposed to the sulfadiazine toxicity. In conclusion, I think we have two conditions in the lungs, and two in the kidneys. In the kidney, there was an underlying nephritis, with a superimposed sulfadiazine reaction.

DR. FLETCHER COLBY: Could not the left-sided renal pain with gross hematuria be explained in some other way than by a drug reaction—that is, by something such as a renal infarct? Gross hematuria and pain in a sulfadiazine reaction are unusual, it seems to me, especially when we do not find crystals in the urine. I do not remember any patients with gross hematuria from sulfadiazine, and I do not remember any who have had pain as the prominent symptom.

DR. TALBOTT: Do you think that the ureter was plugged on that side?

DR. COLBY: I do not know.

DR. CHAMP LYONS: I do not believe we know everything about the renal complications of sulfanilamide therapy. The kidney content of sulfanilamide and sulfadiazine is apparently a reflection of the blood concentration of the drugs, but sulfathiazole and sulfapyridine may be present in the kidney in concentrations above the blood content of sulfonamides. Two types of renal complications occur: one is a toxic effect on the tubules, and the other results from the precipitation of crystals of the free or conjugated drug; both produce hematuria. Sulfathiazole and sulfapyridine crystals may precipitate out and obstruct the kidney tubules, pelvis or ureters, but sulfadiazine crystals, in my experience, are limited to the pelvis and ureter—they do not precipitate in the kidney tubules. Hence, in sulfadiazine therapy, the presence of crystals and blood in the urine suggests ureteral obstruction by crystals. In this case of hematuria without crystalluria, I should consider the kidney lesion an acute toxic nephritis due to sulfadiazine or some other agent.

DR. TALBOTT: You think the pain might come from a toxic reaction rather than from the crystals? I had attributed it to the formation of crystals.

DR. LYONS: Left costovertebral pain and tenderness may occur without crystal formation. In painful crystalluria due to sulfadiazine, there is usually the flank pain of ureteral colic. I am here to see what Dr. Mallory is going to say about the kidneys, because I am puzzled about the clinical interpretation of hematuria in sulfonamide therapy.

DR. ALLAN M. BUTLER: I missed the rationale of the alkalization of this patient. Did Dr. Talbott

want to give him alkali to provide the maximum solubility for the hemoglobin or for the sulfadiazine in the urine or for some general reason because of the presence of renal damage?

DR. TALBOTT: The last two, in the presence of hematuria.

DR. BUTLER: If it is the last two, I should question the wisdom of alkali, because I do not believe we have very definite evidence that alkali within the pH range of urine changes to any appreciable degree the solubility of any known sulfadiazine derivatives.

DR. LYONS: Then you have not accepted Flippin's<sup>1</sup> results on the diminished incidence of crystalluria in patients receiving soda bicarbonate along with sulfonamides?

DR. BUTLER: For the reason that, if I remember the paper, he had no control of the urine volume. Is that the one he read at the meeting of the American College of Physicians last spring?

DR. LYONS: Yes.

DR. TALBOTT: According to reports in the literature,<sup>2,3</sup> the acidity of the urine is a most important factor. The solubility of a sulfonamide at pH 7.5 is nearly double that at pH 6.0. This fact should be appreciated by all who use the drugs, since alkalization of the urine is a simple and harmless procedure.

DR. BUTLER: The work of Sunderman and Pepper<sup>2</sup> indicates some increase in the solubility of sulfathiazole. The bulk of evidence shows no increase in that of sulfanilamide or sulfapyridine. So far as I know, there is no quantitative evidence for sulfadiazine.\*

DR. LYONS: I believe the clinical observation of decreased incidence of crystalluria is sufficient to make it likely that alkalization may increase the solubility of free sulfonamide crystals without affecting the conjugated sulfonamide derivatives.

DR. BUTLER: I agree that there is a possibility, because there is considerable evidence that there are derivatives of sulfonamides excreted in the urine whose identity has not been established; such derivatives may have an increased solubility with a pH of 7.8.

DR. LYONS: Do you agree that the present evidence warrants the alkalization of the patient? Is that unfair to assume?

DR. BUTLER: I am not sure. According to the third criterion, you apparently believe you are doing something to protect the injured kidney by alkali. Does anyone know whether that is so?

DR. TALBOTT: In a transfusion reaction, we are certain that alkali helps.

\*Dr. Butler reports that since this conference he has learned of unpublished work showing that the solubility of urinary sulfadiazine may increase as much as fivefold with an increase in urinary pH from 5.5 to 7.8. He has therefore requested that this information be added to this discussion since it suggests that urinary alkalization should specifically be beneficial with sulfadiazine therapy.

DR. BUTLER: There, one is dealing with the first criterion, when alkalization does make sense. But does it for the third purpose?

DR. MALLORY: The patient under discussion did not have hemoglobinuria but hematuria.

#### CLINICAL DIAGNOSES

Lobar pneumonia (Type 9 pneumococcus).

Nephritis.

Uremia.

#### DR. TALBOTT'S DIAGNOSES

Chronic nontuberculous pulmonary infection.

Pulmonary fibrosis.

Pneumococcal pneumonia, Type 9.

Sulfadiazine reaction.

Nephritis, ? acute or chronic.

#### ANATOMICAL DIAGNOSES

Lobar pneumonia.

Chronic pulmonary fibrosis, with emphysema.

Acute glomerular nephritis.

Arteriosclerosis, aortic and iliac.

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: Autopsy showed evidence of old chronic pneumonitis, with extensive pulmonary emphysema and fibrosis. It also showed a lobar pneumonia in the left lower lobe and extensive fresher pneumonia scattered throughout the other lobes. The kidneys were a little large, weighing 400 gm. When the capsule was stripped backward, the surface puckered somewhat, indicating that the substance was slightly edematous. The capsule stripped very easily, disclosing surfaces that showed a few red flecks. Most careful examination of the pelves, of the ureters and of the substance of the pyramids and cortex under the dissecting microscope showed no crystals anywhere. Microscopic sections showed a very acute glomerulonephritis, but characteristic enough so that I have not the slightest doubt about the diagnosis and there is no evidence of tubular damage.

DR. TALBOTT: You found no microscopic evidence of sulfadiazine toxicity?

DR. MALLORY: I should doubt if the drug ever got through the glomeruli.

DR. BUTLER: Did the picture account for the number of white cells in the urine?

DR. MALLORY: Not too well; it accounted for the gross hematuria well enough, and pain in the back is not uncommon with an acute glomerulonephritis.

DR. BUTLER: Was there a good deal of what Addis<sup>4</sup> calls "degenerative changes"?

DR. MALLORY: Not much—the lesion was too acute. The average glomerulus contained thirty to fifty polymorphonuclears, whereas seven to

twelve is about the normal number. There was also definite, though early, proliferation of endothelial nuclei. I do not believe one can seriously question the diagnosis of glomerulonephritis.

DR. LYONS: Feinstone and his co-workers<sup>5</sup> reported only tubular nephritis from sulfadiazine. Is it possible that sulfadiazine could cause glomerular damage?

DR. MALLORY: I am reluctant to believe any chemical substance can cause glomerular nephritis. I would rather believe that the sulfonamide so altered the immune reactions of the body that the latter reacted to a pneumococcus as if it were a streptococcus.

DR. BUTLER: How sure are you that the preparations in which the kidney was fixed did not destroy the sulfadiazine crystals?

DR. MALLORY: We looked for crystals with the dissecting microscope in unfixed tissue.

DR. TALBOTT: There were no crystals in the sections?

DR. MALLORY: No; in other cases of sulfonamide nephrosis, we have had no difficulty finding the crystals, usually in large numbers in the pelvis and frequently in significant numbers in the renal parenchyma.

DR. TALBOTT: Do you routinely put them in absolute alcohol?

DR. MALLORY: We have had no luck in preserving crystals in sections with any fixative or embedding method.

DR. ALLEN G. BRAILEY: Is it not possible to get a double infection, streptococcal as well as pneumococcal?

DR. MALLORY: I suppose that is conceivable.

#### CASE 28212

#### PRESENTATION OF CASE

A sixty-seven-year-old Portuguese-American fisherman was admitted to the hospital because of abdominal pain of several hours' duration.

The patient was essentially well until the night before entry, when he noted gradual onset of periumbilical pain, which rapidly became worse. The pain was sharp, severe and fairly steady, although it was worse when gurgling occurred in the abdomen. On the morning of entry, the pain subsided and shifted to the midline below the

umbilicus. The patient vomited once, regurgitating only food that he had eaten that morning. During the illness, he passed neither gas nor feces.

Twelve years before entry, he was operated on for "stomach ulcers" at a community hospital, following four days' study. Subsequently he had frequent attacks of gas pains in the upper abdomen, which were always relieved by the taking of food. These pains were similar to the one that brought him to the hospital except that this last attack was not relieved by food.

On admission, the patient appeared well developed but thin. He was groaning from pain. The abdomen was distended and tympanitic, with diffuse spasms of the muscles. Although the markings of loops of bowel were visible, there were only occasional bursts and tinkles of high-pitched, loud peristalsis. There was dullness in both flanks, which appeared to shift when the patient was lying on his side. No masses were palpable. Tenderness seemed to center in the left upper quadrant. Rectal examination demonstrated a bulging, soft, boggy posterior cul-de-sac, which was not tender. There were no feces or gas in the rectum. The heart and lungs seemed normal.

The blood pressure was 160 systolic, 90 diastolic. The temperature was 99.5°F., the pulse 88, and the respirations 20.

Examination of the blood showed a white-cell

a notable absence of spasm. Unless the peritoneum is involved by infection, spasm, at least of an involuntary nature, will not occur. We know that if one puts a balloon in the small bowel and distends it so that very severe peristaltic pain is initiated in normal human beings, there is absolutely no spasm whatever; the abdomen is soft and flaccid. However, it is possible for certain persons to react to pain by voluntary spasm, and I am rather inclined to think, because of the essentially normal temperature, blood count and other evidence that does not point to infection, that the spasm described was probably voluntary and not involuntary, and was simply a reaction of the patient to discomfort.

The pain was periumbilical in the beginning and shifted to the midline below the umbilicus. That may be of some significance and might possibly indicate that whatever was the cause of the obstruction had moved downward a little bit. Also, because the pain subsided after admission, the patient's condition may have improved temporarily, and the degree of distention within the intestine may have become less. What relation this obstruction had to the previous history of operation for ulcers is problematical; since no details are given concerning the previous operation, it is perhaps not worth while for me to speculate about, except to say that gastric ulcers may become malignant and that the patient might have developed peritoneal metastases, although

be the cause of repeated attacks of small-bowel pain culminating in obstruction such as this. Cancer of the small bowel, carcinoma, sarcoma and lymphoma are quite rare but might be present.

Other possible causes that might be mentioned are changes in the circulation—an embolus, for example, since the patient is in the arteriosclerotic age, or mesenteric thrombosis. These usually are a little more severe and intense and more sudden in origin and are usually accompanied by a higher white-cell count than this man had and usually do not tend to improve once they have become well established. The nervous causes of intestinal obstruction are rare, but they are not unknown. We have recently had a patient who had such a small-bowel obstruction,—very possibly from a derangement of autonomic and vagus activity,—but ileus of that nature is usually secondary to a lesion elsewhere, such as one of the biliary or genitourinary tract.

It seems unlikely to me that this patient had pancreatitis, perforated ulcer, renal or biliary colic or a lesion of that sort. The symptoms are consistent with a diagnosis of middle or low small-bowel obstruction whose cause is not entirely clear, but I think, on the chances, one would have to put postoperative obstruction or obstruction due to an adhesive band as first choice.

DR. ARTHUR W. ALLEN: We connected the acute small-bowel obstruction with the previous surgery. We knew that the patient had had some sort of operation on his stomach. We did not know what kind. Dr. Charles Mixter, Jr., made a very excellent effort to get the Miller-Abbott tube into the small bowel under the fluoroscope. It seemed to leave the stomach and go to the right for a certain distance, but no farther, and then bounce back into the stomach. Consequently, without waiting and struggling with it any more, we decided that we had better explore the patient, since our experience with Miller-Abbott tubes that fail to pass the pylorus readily in small-bowel obstruction has been very unfortunate. If we had waited until morning, I think we could not have rescued this man because we could not have decompressed the small intestine with the Miller-Abbott tube.

At operation, we found that a subtotal gastrectomy with an antecolic anastomosis had been done, but he did not have a loop of small bowel threaded through this as we had suspected. Why not, I do not know, because it makes a beautiful trap. Also, the jejunum had been anastomosed over the transverse colon, with a very short loop that may have accounted for some of the postoperative symptoms. We were able to thread the Miller-Abbott tube down through the anastomosis and the distal link of jejunum very nicely on the operating table, and by suction from above we

slowly decompressed the small bowel. The tube obviously had gone down into the proximal blind loop of jejunum during the manipulation prior to laparotomy.

At a point approximately 40 cm. from the ileocecal valve, we encountered a large bolus of material within the lumen of the bowel back of which this obstruction had taken place. At first, we thought it probably was a mass of worms, but it turned out to be the pulp, in four sections, of an entire orange. The patient had probably swallowed these sections one after another, but they had got together in a long elliptical mass, which had stuck in this spot. Through a small incision in the bowel, we extracted this foreign body and closed the bowel. The decompression being satisfactory with the Miller-Abbott tube on the table, we were quite happy about it. If we had not been able to decompress the bowel in this manner, we should have emptied it of its contents by other means. In intestinal obstruction of this duration, the patient rarely survives the toxic effects of such material. The risk of leaving it within the bowel is very great. I have tried to locate some of Dr. George Monks's<sup>1</sup> original tubes on which to thread the intestines under these conditions—I once had one of these tubes in my possession and regarded it as a relic. Dr. David Cheever,<sup>2</sup> a few years ago, revived and used such a method. Recently, Wangenstein<sup>3</sup> has called attention to the value of a similar maneuver.

Aside from a brief pulmonary complication, this man did very well.

A PHYSICIAN: Is it not true that foreign bodies will stop at that location?

DR. ALLEN: It is the narrowest portion of the ileum and is somewhere in the neighborhood of 40 cm. from the ileocecal valve. Why there, I do not know. That is also the common site of a Meckel's diverticulum. Does Dr. Mallory know whether this has anything to do with the narrowing of the bowel in this location?

DR. TRACY B. MALLORY: No.

DR. ALLEN: Anatomically, that is considered the narrowest area in the small bowel.

#### CLINICAL DIAGNOSIS

Intestinal obstruction.

#### DR. SMITHWICK'S DIAGNOSIS

Small-bowel obstruction due to adhesive band.

#### ANATOMICAL DIAGNOSIS

Small-bowel obstruction due to phytobezoar.

## TREATMENT OF PNEUMONIA IN THE HOME

THE introduction of chemotherapy with the sulfonamide drugs has revolutionized many beliefs concerning the treatment of acute infectious diseases. Not only has the mortality from many infections been markedly reduced, but most of the laborious methods of treatment either have been rendered totally unnecessary or are now resorted to only infrequently.

The severely ill patient with pneumonia—tense, flushed, markedly dyspneic and cyanotic, enclosed in an oxygen tent and with a distended abdomen covered with poultices or stupes—was a common sight in any large medical ward throughout the

pneumonia season only a few years ago. It is now rare to find such a case for demonstration to students, even in large general hospitals. This change is due in part to the fact that the diagnosis of pneumonia is being made early in the course of the disease, but particularly to the institution of chemotherapy with effective sulfonamide drugs as soon as the existence of an acute pulmonary infection is suspected.

The use of the first sulfonamide drugs—sulfanilamide and later sulfapyridine—was accompanied by severe toxic effects that necessitated great vigilance and many special diagnostic and therapeutic procedures. For this reason, and because persistent and adequate treatment with the sulfonamides is essential for the best results, most physicians believed that it was only fair to themselves and to their patients that sulfonamide therapy should be carried out in hospitals, where adequate personnel and other facilities are more readily available for the management of problems as they arise.

As physicians acquired more experience in the use of the sulfonamide drugs and as new derivatives became available that were more effective and at the same time gave fewer reactions, the attitude toward hospitalization changed materially. The physician is now in a position to administer effective therapeutic doses of such drugs as sulfathiazole and sulfadiazine in the home and to carry out the essential observations with a minimum of effort.

Elsewhere in this issue of the *Journal*, there is a report on the treatment of 132 cases of pneumonia with sulfathiazole in the home. The patients were from among the poor residents of Boston who could not afford to pay for the services of private physicians. The success of this venture is indicated by the very low mortality—3.8 per cent—and by the rarity with which complications of either the disease or the treatment were encountered. The results are all the more remarkable since a large percentage of the patients were over fifty years old and some of them had positive blood cultures. These favorable results are due

in large measure to the early institution of treatment and to the diligence and interest of the physicians engaged in this work. Nevertheless, most of the procedures that these district physicians were called on to do could easily be carried out by any private practitioner. This excellent work has served to relieve, in some measure, the marked overcrowding of the public wards of Boston hospitals during the season when respiratory infections are prevalent.

Some degree of caution is still necessary, especially since all the newer drugs give rise to untoward reactions, particularly in the urinary tract. The practice of forcing fluids is to be stressed, particularly in patients treated with these drugs in the home, and special precautions should be taken with those who are suspected of having impaired renal function. Blood counts must be taken frequently in patients who require prolonged treatment (over periods lasting more than two weeks), to forestall the occurrence of agranulocytosis. The danger that the patient will not carry out the treatment or will discontinue it too soon is perhaps of greater consequence in the domiciliary management of severe infections like pneumonia. The success of sulfonamide treatment in this disease, as in most infections treated with these agents, depends on adequate and continuous treatment until a complete cure is effected.

The successful experiences of the Boston Dispensary physicians are not unique and are not dependent entirely on a highly trained "team." Physicians in private practice can obtain similar results. This is demonstrated in a recent report by McClure,\* who reviewed 386 cases of pneumonia treated by private practitioners in Ontario. Sulfapyridine alone was used in the treatment of 92 per cent of these cases, most of which were associated with type-specific pneumococci. It is of interest that the mortality in the cases treated with sulfapyridine was 3.7 per cent, which is almost identical with that reported in the patients treated in Boston with sulfathiazole. It is also worthy of note that the average total amount of sulfapyridine

used was only half as much as that of sulfathiazole. The difference may very well be related to the more frequent and severer nausea and vomiting that accompany sulfapyridine treatment and induce both patient and physician to discontinue treatment sooner than might otherwise be deemed necessary.

### A COMPLIMENT

Under the title, "*The New England Journal of Medicine*," the following editorial appeared in the April 15 issue of the *New York State Journal of Medicine*:

In a letter to the *New York Times* of March 25, 1941, Dr. Henry R. Viets of Boston, quoting an editor in that paper, of March 22, entitled "A Yale Genealogy says:

It would be interesting to trace the lives and usual early deaths of magazines that have taken the name of New England. . . . One stalwart in that line is the *New England Journal of Medicine*, the first journal of medicine in this country, if not in the world, which has continued, despite changes in form and of name in uninterrupted existence since 1812. The name "New England" was held from 1812 to 1828, when the magazine became the *Boston Medical and Surgical Journal*. In 1928, the name again became *New England Journal of Medicine*.

We are beholden to Dr. Viets for this interesting information about this stalwart publication. Always an appreciative admirer of the contents of the *New England Journal of Medicine*, the *NEW YORK STATE JOURNAL OF MEDICINE* now finds itself viewing with reverence this additional, and until now to us unknown attribute of great age of our northerly sister. We are content to have the respectable, even genteel, name of New England carried forward from generation to generation by such a worthy vessel. The episode of the Boston wild oats, from 1828 to 1928, has already been forgiven, and will soon be forgotten. In another century, not one of us now living will remember it.

In the light of this new learning from the pen of Dr. Henry Viets, historian, we shall henceforth turn the pages of our copies of the *New England Journal of Medicine* gently, with great delicacy. And as they rustle under our disturbing touch, they will remind us of the glories of her youth, the crinolines of Dolores Madison, the exploits of Commodore Perry and Captain Lawrence, and of the *Constitution* and the *Guerriere*, *Old Ironsides*, Tecumseh's Conspiracy, and Harrison at Tippecanoe.

This stalwart, "northerly sister," admitting that great age in itself is not to be taken too seriously and is often, indeed, a subject to be avoided in conversation with the truly old, appreciates

\*McClure, W. B. Chemotherapy in pneumonia cases treated by private practitioners. *Canad. M. A. J.* 45:26-28, 1941.

the admiration, reverence and delicate humor of the *New York State Journal of Medicine*. Perhaps, along with Captain Lawrence, Commodore Perry and Dolly Madison's crinolines, the rustling pages will evoke a memory of the dry, salubrious chuckle of Dr. Holmes.

## OBITUARY

### FREDERICK TAYLOR LORD

1875-1941

FREDERICK TAYLOR LORD was born in Bangor, Maine, on January 16, 1875. His boyhood was spent in Lexington, Massachusetts, and he prepared for college in the public schools of that town. In 1897, he obtained from Harvard his degree of bachelor of arts. His excellent reading knowledge of French and German was doubtless acquired during his college days. Only three years later,—in 1900,—he graduated from the Harvard Medical School. His first knowledge of clinical medicine must have been acquired in the Massachusetts General Hospital during his internship, for at that time there were no clinical clerkships at Harvard and fourth-year students were not allowed in the wards. From the time he entered the hospital as a house officer until he retired as a visiting physician in 1935, his life was intimately connected with the Massachusetts General Hospital.

On finishing his internship, Dr. Lord at once made a beginning in private practice, but at the same time he began research in bacteriology at the Massachusetts General Hospital under the personal direction of Dr. J. Homer Wright, who was as skilled in bacteriologic technic as he was in pathology. At the outset, he received help and inspiration from Dr. William H. Smith, who had worked some time in the laboratory when Dr. Lord was a novice. Undoubtedly Dr. Wright and Dr. Reginald H. Fitz were the two men who influenced him most. His first study published from the laboratory—his second publication—dealt with the influenza bacillus, which he cultivated from 11 cases of acute and 18 cases of chronic infection of the upper respiratory tract. This paper appeared in 1902. Additional studies of the influenza bacillus appeared in 1905. His work on influenza made such a favorable impression on Dr. Osler that he was asked not later than 1905 to prepare the section on influenza for Osler's system of medicine. In this monograph and the two subsequent ones, Dr. Lord presented a detailed analysis of the cases of influenza admitted to the Massachusetts

General Hospital over a period of years. Prior to his work in bacteriology, he published an analysis of 26 cases of so-called "typhoid spine" that he collected from the literature. In its preparation, his knowledge of French and German stood him in good stead.

Diseases of the respiratory tract were always his special interest, dating from his early work with the influenza bacillus. With Dr. Walter James, he contributed the chapter "Diseases of the Pleura" to Osler's system, which was published in 1907.

This early bacteriologic work was carried out in confined quarters. Dr. Means called it a "cubby-hole." Finally, after many years, he acquired a more adequate laboratory, in which he and Dr. Robert N. Nye carried out valuable studies on the biology of the pneumococcus. Pneumonia and tuberculosis were his major subjects of study in later years. He was one of the first to investigate the antipneumococcus serums, and he did much to make serum therapy in pneumonia available to the physicians in Massachusetts through his connection with the Massachusetts Department of Public Health. In collaboration with Drs. Roderick Heffron and Elliott S. Robinson, he wrote two books on the treatment of pneumonia; the second of these dealt with chemotherapy as well as serum therapy.

In 1915, his valuable book, *Diseases of the Bronchi, Lungs and Pleura*, appeared, and ten years later a second edition, thoroughly revised and including a section on pulmonary tuberculosis. In addition to a most thorough study of the literature, this work contains a great deal of original material based on Dr. Lord's experience at the Massachusetts General Hospital and in his private practice. The most careful analysis of medical records is presented. He followed the course of patients for years after he had last seen them. For example, he wrote that of the 65 patients with bronchial asthma in his series whose subsequent courses were known, 11 were completely free from asthma for two to six years after their last visit. This statement, which occupies only three sentences of his text, represents a great deal of laborious work in record making and correspondence with former patients, a task that few physicians would undertake. The book was dedicated to the memory of Dr. Reginald H. Fitz. It is clear that his medical career was largely patterned after that of Dr. Fitz. In the writings of both are the same thorough knowledge of the literature and the same analysis of carefully recorded clinical and pathological observations. This book of outstanding value has never received the recognition it deserved. It is still one of the best treatises on diseases of the respiratory organs.

Dr. Lord was a remarkably successful teacher. Year after year, he gave a course for practitioners, consisting of one exercise a week over a period of many weeks. As many as a hundred physicians attended this course at one time.

His consulting practice for many years was one of the largest, if not the largest, in Boston. The bag filled with diagnostic equipment, which he took with him on consultations, was said to be the largest on record. He examined his patients with meticulous care and made careful records. He made good use of this abundant material. In support of this statement, the following facts are cited. In the birthday volume presented to Sir William Osler in 1919, Lord reported an analysis of 100 cases of pulmonary abscess. In 1925, only six years later, he was able to add 127 cases that he had observed and studied.

During the last seven years, his interests broadened, and problems of public health became his chief concern. He served on advisory committees of both the Boston City and the Massachusetts State departments of health.

As a man, he was kindly, serene and modest. He was charitable of the faults of others and was not given to criticism. But he could speak out fearlessly when an incompetent man was proposed for a position of responsibility. He was in the best sense of the term a self-made man. He carried on his studies and hospital work without pay and largely supported his laboratory at his own expense. He showed the manner of man he was by his work. He talked little and did much. He was a true scholar and scientist, a physician without guile and a man whose memory we cherish and honor.

J. H. P.

## MEDICAL EPONYM

### PAGET'S DISEASE (PRECANCEROUS ECZEMA)

This condition was described by Sir James Paget (1814-1899) in a paper, "On Disease of the Mammary Areola Preceding Cancer of the Mammary Gland," that appeared in the *St. Bartholomew's Hospital Reports* (10:87-89, London, 1874). A portion of the text follows:

I believe it has not as yet been published that certain chronic affections of the skin of the nipple and areola are very often succeeded by the formation of scirrhus cancer in the mammary gland. I have seen about fifteen cases in which this has happened. . . . In all of them the disease began as an eruption on the nipple and areola. In the majority it had the appearance of a florid, intensely red, raw surface, very finely granular, as if nearly the whole thickness of the epidermis were removed; like the surface of very acute diffuse eczema, or like that of an acute balanitis . . . in every case which I have been able to watch, cancer of the mammary gland has followed within at the most two years, and usually within one year. . . .

The formation of cancer has not in any case taken place first in the diseased part of the skin. It has always been in the substance of the mammary gland, beneath or not far from the diseased skin, and always with a clear interval of apparently healthy tissue.

### COMMITTEE ON MATERNAL WELFARE

#### CASE HISTORY: RUPTURE IN TUBAL PREGNANCY CAUSING FATAL PERITONITIS

A thirty-four-year-old primipara whose past history was entirely irrelevant and whose physical examination was quite normal was seen six weeks after her last catamenia. While working about the house, she was seized with severe abdominal pain, and the physician who responded to her call took her immediately to the hospital, where a diagnosis of ectopic pregnancy was made and operation advised. The patient's husband refused permission for operation, and three days later the patient went home. Eight days after discharge, she returned to the hospital in very poor condition, with a rapid pulse and a low blood pressure. An operation was immediately performed. The abdomen was full of blood, and the contents of the left tube were removed. There were many adhesions about this tube, whose removal resulted in considerable trauma to the adherent intestine. The patient was transfused, and the abdomen was closed, a drain being left at the base of the left adnexa. For twelve days, recovery was satisfactory. At the end of this time, signs of intestinal obstruction appeared, requiring a subsequent operation. At operation, the intestines were found to be kinked and adherent, and an abscess mass was present in the region of the removed left tube. The patient was again transfused, but her condition continued to grow worse until death, which occurred ten days following the second operation.

*Comment.* This fatal case of a rupture in an extrauterine pregnancy was due solely to ignorance or stubbornness on the part of the patient's husband; the medical profession was in no way to blame. The diagnosis was made at the onset of the illness; operation was advised and was refused. The patient went home and returned to the hospital in very poor shape after a second hemorrhage. Had the operation been performed at the time of the first attack, simple surgery would have been sufficient. The operation for the subsequent attack with greater hemorrhage was complicated by the intestinal adhesions surrounding the ruptured tube. These were freed during the salpingectomy, and much raw surface was present that would not have resulted had the operation

been performed earlier, as the surgeon desired. At the second operation, performed because of signs of intestinal obstruction, an abscess was found at the base of the left tube, this was caused by the rupture of the intestine. The patient apparently recovered from the intestinal obstruction and died of general peritonitis.

Each year, several patients die of the complications of tubal pregnancies. Some of these deaths can be attributed to wrong diagnosis on the part of the physician, or to his inability to appreciate the necessity for laparotomy. Some cases are definitely due to ignorance on the part of the patient, who does not seek medical advice when the early signs of irregular bleeding present themselves.

## COMMITTEE ON ARRANGEMENTS

### PROGRAM SUBSTITUTIONS

On account of the illness of Dr Edwin H. Place, Dr Conrad Wesselhoeft has courteously consented to speak. His subject will be "Mumps as a Military Disease."

The Section of Obstetrics and Gynecology will meet in Perkins Hall, Women's Educational and Industrial Union, 244 Boylston Street, instead of at the Tavern Club as previously announced.

WILLIAM T. O'HANLON, *Chairman*

## WAR ACTIVITIES

### CIVILIAN DEFENSE

#### CHEMICAL WARFARE COURSE

Twenty-five physicians from the First, Second and Third defense regions attended a special course, "Medical Aspects of Chemical Warfare Agents," at the University of Cincinnati College of Medicine, February 23 to 26, inclusive under the auspices of the Medical Division of the United States Office of Civilian Defense with the cooperation of the Chemical Warfare Service of the United States Army. It is expected that the class will be repeated for physicians of other regions in the coming months.

It is intended that physicians who have taken this course will be able to set up similar units of instruction in their own localities and will teach both medical and civilian groups. The students were selected by the regional medical officers in the three eastern regions. There was no charge by the university for tuition and materials, the course being offered as a contribution to the war effort. Travel and living expenses of the students were financed locally through state and local defense councils.

## NEW HAMPSHIRE MEDICAL SOCIETY

### NOTE

The new head of the New Hampshire State Board of Health is Dr. Ralph E. Miller of Hanover, assistant dean and associate professor of pathology at Dartmouth Medical School. He succeeds Dr. George C. Wilkins of Manchester, who recently retired after having served in that capacity for many years.

### DEATH

WEBBER — NORMAN B. WEBBER, M.D. of Manchester, died February 22.

Born in Thetford, Vermont, on August 15, 1875, Dr. Webber graduated from the University of Vermont College of Medicine in 1903 and had practiced medicine in Manchester since 1904. He was associated with the Notre Dame and Elliot hospitals. He was a member of the New Hampshire Medical Society and the American Medical Association.

## MISCELLANY

### SCHERING AWARD WINNERS

Winners of the Schering Award for 1941 have just been announced by the Association of Internes and Medical Students. Fred Feldman, 42 Albany Medical College, and Cesare Lombroso, 47 Johns Hopkins University School of Medicine, have been awarded first and second prizes respectively, by the Committee of Judges, a group of outstanding American investigators. Elizabeth Brown, Albany Medical College, and Clarence Denton, Long Island College of Medicine, have been awarded third prize. The subject for the 1941 competition was "The History of Endocrine Research."

The Schering Award, established by the Schering Corporation and conducted by the Association of Internes and Medical Students, offers two tuition scholarships of a year and a half year, respectively, to be granted for the best papers dealing with some aspect of endocrinology submitted by undergraduate medical school students in the United

### DEATHS

BREFFN — JOHN J. BREFFN, M.D. of Lowell, died February 3. He was in his fortieth year.

Born in Lowell, the son of the late John J. and Harriett (Greenhalge) Breen, he received his degree from St. Louis University School of Medicine in 1928. After serving his internship at St. John's Hospital, Lowell, Dr. Breen began general practice in Lowell. He was associated with the staffs of St. John's Hospital, the Lowell Visiting Nurses Association and the Lowell Day Nursery, and was a member of the Massachusetts Medical Society and the American Medical Association. At the time of his death, he was awaiting call for active service with the United States Army.

WHEELER — JOHN B. WHEELER, M.D. of Burlington, Vermont, died May 1. He was in his eighty-ninth year.

Born in Stowe, Vermont, Dr. Wheeler received his degree from Harvard Medical School in 1879. He was an intern at the Massachusetts General Hospital. From 1881 to 1924 he was associated with the surgical department of the University of Vermont College of Medicine — as instructor, clinical professor and professor. He was one of the founders of the American College of Surgeons and the New England Surgical Society. He was a fellow of the Vermont State Medical Society and the American Medical Association, and was a former member of the Massachusetts Medical Society.

Two daughters and a sister survive him.

States or Canada. In all, papers were submitted by students representing twenty-four medical schools, an indication of the wide interest and response occasioned by the competition.

Plans for the Schering Award competition for 1942, which will again be sponsored by the Association of Internes and Medical Students, are being formulated. The subject for this year's paper, as well as the full panel of judges, will be announced shortly.

## ANNUAL PRIZE SUBSCRIPTION

The annual prize subscription offered by the *New England Journal of Medicine* for the best undergraduate contribution to the *Tufts Medical Journal* has been awarded to Mathew Ross, '42, for his paper "Acute Appendicitis of Childhood and Its Differential Diagnosis," which appeared in the March, 1942, issue. The paper "Constitutional Medicine," by D. A. Freedman, '43, received honorable mention; it appeared in the November, 1941, issue of the journal.

## NOTES

At the recent meeting of the American Heart Association in New York City, Dr. Paul D. White, of Boston, was elected president for the ensuing year.

Two important appointments to the staff of the Harvard Medical School, effective July 1, were recently announced by the University. Dr. Rene Jules Dubos has been appointed George Fabyan Professor of Comparative Pathology and Professor of Tropical Medicine, to succeed Dr. Ernest E. Tyzzer, who becomes professor emeritus. Dr. George W. Thorn has been appointed Hersey Professor of the Theory and Practice of Physic and Physician-in-Chief of the Peter Bent Brigham Hospital, to succeed the late Dr. Soma Weiss.

## REPORT OF MEETING

### NEW ENGLAND PEDIATRIC SOCIETY

A regular meeting of the New England Pediatric Society, held at Longwood Towers on January 14, was presided over by Dr. R. Cannon Eley. An obituary of the late Dr. Kenneth Blackfan was read. The speaker of the evening was Dr. Joseph W. Ferrebee, of the new Harvard School of Dental Medicine, who discussed the dental problem as related to the practice of pediatrics.

At present, the cost of dental care is equal to or even greater than that for medical treatment. Twenty per cent of those examined by the military authorities in the present selective-service group are found to have reason for rejection in the condition of their teeth. The repair of teeth, which accounts for two thirds of the dentists' work, is much more costly than prophylactic treatment. Furthermore, this need will become more urgent with the natural regression of the teeth attendant on our civilized habits of eating and preparing foods. It is well known that milling removes 90 per cent of certain vitamins, for example.

The problem for the pediatrician springs partly from the fact that the calcification of the primary dentition takes place from midterm on, whereas secondary calcification occurs from term through early childhood. Contrary to popular belief, primary dentition is not unimportant, for at that time normal chewing habits begin that result in proper spacing of the teeth and development of

the jaw. And proper spacing of the teeth prevents the dirt and pyorrhea that accompany faulty cleaning. Furthermore, caries may be spontaneously walled off in a few weeks by secondary dentine if the person is placed on good general home care and proper diet.

At present, the maximum incidence of visits to the dentist occurs in the age group from fifteen to twenty-one years, whereas the minimum is in those from three to eleven years. For better results, these should be reversed, so that proper prophylaxis might be carried out. The essential factors in prevention of later dental troubles are proper home care of the teeth, an adequate diet and frequent visits to the dentist at an early age.

## BOOK REVIEWS

*Lectures on War Neuroses.* By T. A. Ross, M.D. 12°, cloth, 116 pp. Baltimore: Williams and Wilkins Company, 1941. \$2.00.

This brief volume is a valuable addition to the subject of war neuroses. It was written by a physician who had a large experience in World War I and subsequently continued to be interested in civilian neuroses in his practice of medicine. He has been in touch with the subject in World War II, and he gives some brief notes on the experiences of the English soldier escaping from Dunkirk and the effect of bombing on the public.

The volume is divided into only four chapters: one presents a preliminary discussion of neuroses in general; the second deals with the acute war neuroses; and the third and fourth discuss the more chronic conditions. The material in these chapters has been given as lectures at medical centers in the last twelve months.

Full of sound common sense and written by a man who is completely familiar with his material, this little book is an outstanding contribution to the subject. It is, moreover, timely, and should be put in the hands of every medical officer in charge of soldiers, sailors or civilians likely to suffer from neuroses incident to modern warfare.

*Outline of Industrial Medical Practice.* By Howard E. Collier, M.D. (Edin.), Ch.B. 8°, cloth, 440 pp. Baltimore: Williams and Wilkins Company, 1941. \$5.00.

Out of the kaleidoscopic development of manufacturing processes during the past two decades, industrial medicine has emerged as a new field in which the general practitioner finds few landmarks or familiar paths. It is especially to orient the run-of-the-mine physician in the problems of modern industrial medicine and to furnish the plant physician with a working guide to administrative practice that this book has been prepared.

In addition to providing an exceptionally concise and practical handbook on all phases of occupational hygiene this work is unique in emphasizing the importance of group illness in industrial medicine. Since occupational disease is something more than the aggregate of the illnesses of the individuals in the group, the plant physician as well as the health officer, must learn to think in terms of possible common causes of group illness. The sector on industrial psychology is the clearest and most constructive discussion that the reviewer has seen of that vexed but significant field.

The bibliography is well chosen for the physician who may wish to look farther into some of the sources of industrial medicine.

## MEDICINE AND AIR SUPREMACY\*

JOHN F. FULTON, M.D.†

NEW HAVEN, CONNECTICUT

GEORGE CHEYNE SHATTUCK, the younger (1813-93), whose father, George Cheyne Shattuck, the elder (1784-1854), left the bequest that led to the founding of this lectureship, died early in 1893, and Osler,<sup>1</sup> who gave the fourth lecture of the series in that year, chose for his subject "Tuberculous Pleurisy," a theme in which the younger Shattuck had been interested since his early days in Paris, when he studied under the great French clinician, Louis. Shattuck's son, Frederick Cheever Shattuck (1847-1929), was, like his father and grandfather, a great force in New England medicine. The Shattucks were men of humor, forthright candor and passionate loyalty to the traditions of this country. Their humor is well illustrated in a lively encounter between Frederick Cheever Shattuck and Harvey Cushing, who gave the Shattuck Lecture in 1913.<sup>2</sup> Dr. Shattuck had read Cushing's account of the Western Reserve and its traditions,<sup>3</sup> and was horrified to find the word tomahawk misspelled. Dr. Cushing, his secretariat and the Cleveland proofreaders had all passed "tommyhawk"—spelled like "tommy-gun." This was too much for Frederick Cheever, who immediately commandeered conveyance to the Peter Bent Brigham Hospital, and, wearing a pair of enormous plus fours, dashed in the side door of Dr. Cushing's office to tell him that the Moseley Professor of Surgery, who had been born in the Western Reserve out among the Indians, should know the spelling of tomahawk; not content with this, he wrote Cushing a letter referring him to the *Century Dictionary*.

\* \* \*

I have said that the Shattucks were men of intense loyalty to this country's traditions, and when your committee requested aviation medicine as the subject of this discourse, it seemed obviously

a theme wholly appropriate for a lecture devoted to the memory of this remarkable line of American physicians; moreover, a topic with military implications is not without precedent, for just twenty-five years ago, — in June, 1917, — Dr. Walter B. Cannon gave a Shattuck Lecture on traumatic shock.<sup>4</sup> In accepting the honor, I have, however, taken on a heavy responsibility, and one that for various reasons is embarrassing.<sup>5</sup>

The National Research Council and the Office of Scientific Research and Development have followed the policy of classifying as "confidential" or "secret" all topics having to do with offensive instrumentalities of war. The airplane is clearly such an instrumentality, as are many of the devices within the plane designed to improve the performance of the pilot in his rapid, high-altitude maneuvers; so that medicine, perhaps for the first time in its history, has come to be divided, so far as war is concerned, into offensive and defensive spheres. Advances that have to do with increasing the effectiveness of human performance in combat become military secrets, and cannot now be openly discussed. Defensive measures, on the other hand, designed for treating the wounded, either civilian or military, or for prophylaxis, as by inoculation, fall into the category of defensive measures and can be freely described. Aviation medicine falls squarely across the broad categories of offense and defense, and I am therefore obliged to devote attention primarily to the defensive phases of the subject.

It has become obvious, even to the most casual observer, that air supremacy will determine the outcome of the present war. Shipping still has vast importance and we look carefully to our tonnage, but all the ships of the United Nations would become virtually useless without command of the air. Supremacy in aviation is not wholly a question of more and faster planes with greater firing power than the enemy. This, to be ant, but equally so is the

\*The Shattuck Lecture, delivered at the annual meeting of the Massachusetts Medical Society, Boston, May 26, 1942.  
†From the Laboratory of Physiology, Yale University School of Medicine.  
‡Assistant Professor of Physiology, Yale University School of Medicine.

well-selected, well-trained and adequately protected flying personnel. The performance of modern aircraft has far outstripped the physiological limitations of the pilot. The newer combat planes can fly higher than is compatible with life, even when the fliers are breathing pure oxygen. They can perform maneuvers causing centrifugal force of such intensity that blood tends to be drawn away from the brain, a condition that results in transient blindness (blacking-out) and unconsciousness. And, finally, the range of the modern four-motored bombers—some of which can remain for twenty-four hours in the air—has raised problems of pilot fatigue, severe stresses and strains from cold, psychological tension and loss of sleep that impair the performance of flying personnel. It is the responsibility of medicine in its broadest sense, including psychology, psychiatry, physiology and the special branches of clinical medicine, to protect flying personnel from these and many other hazards that they face. The role of the physician in both the offensive and defensive phases of the war effort has therefore become increasingly vital for broad military strategy.

Air supremacy involves not only flying personnel but ground personnel. It is estimated that for every man in the air there are nine or ten men on the ground, both in civilian airlines and in military aviation; men on the ground are as essential as the men in the air, and if the Army should wish 100,000 pilots it must recruit 1,000,000 men. Air supremacy also extends to the men in the aircraft factories, who are exposed to special hazards peculiar to aircraft production. I cannot speak of industrial hazards in aircraft plants, but they are real and their successful handling rests with industrial physicians. In an aviation plant recently visited, 600 from a total of 30,000 employees were treated daily for accidents or illness occurring in the plant—that is, 2 per cent of the total personnel became ill or were injured each day. This is far higher than one would wish or anticipate, and yet with the vast expansion of the past twelve months, such injuries are to some extent inevitable. In a plant that is not expanding, injury rates diminish, but usually only as rapidly as the measures taken for their prevention. The need for industrial physicians in all phases of the war effort continues to be enormous.

To give a more general idea of the scope of aviation medicine, I shall describe a classified bibliography of the subject that is now in the process of publication.

#### LITERATURE OF AVIATION MEDICINE

In recent months, my associates, Dr. and Mrs. Ebbe C. Hoff, and I have had the responsibility

of searching out, listing and classifying all available literature bearing on the medical aspects of aviation. The project was proposed near eighteen months ago, and the labor is now completed, for the bibliography will be published within a few weeks.<sup>6</sup> The subject matter covers a vast range, the principal topics being indicated by the main chapter headings of the bibliography:

1. History and General Aspects of Aviation Medicine.
2. The Special Physiology of Aviation. (This section is divided into nineteen subsections including all the organ systems and special senses.)
3. The Special Pharmacology of Aviation.
4. The Special Psychology of Aviation.
5. Aeromicrobiology. (Bacteriology and immunology in aviation and high altitudes.)
6. Diseases and Accidents in Aviation and Conditions Simulating Flight.
7. Selection and Assessment of Efficiency of Flight Personnel.
8. Training, Performance and Fatigue of Flight Personnel.
9. Protection of Flight Personnel: Preventive medicine and therapeutics of aviation.
10. Aviation and Public Health.
11. Organization of Aviation Medicine.
12. Special Problems.
13. General Studies in Aviation Medicine.
14. Bibliographies.

It may be of interest that, although approximately six thousand separate items were for the author index contains some nineteen thousand names, from which one must infer that those who write on the subject generally write in trios. And this expresses what some of us gradually come to realize: that research endeavor in this field is inevitably co-operative. The flight surgeon uses a pilot or some fellow flight surgeon as a subject of an experiment, sometimes in air, sometimes in a decompression chamber, sometimes in a human centrifuge. When decompression experiments are involved, five or six people generally constitute a team, and their names may appear as co-authors of the report.

The bibliography itself cuts across the scientific periodical literature of all phases of the world, countries, articles from about 1920 onwards having been cited. Of course, the bibliography includes only articles in medical journals.

In passing, one may mention that from the standpoint it would be impossible to work out purely for medical journals. On this point we were fortunately forewarned and at the start adopted the conventions of *A World List of Scientific Periodicals* as a basis for abbreviations; this made possible the citation in conveniently abbreviated form of any scientific journal in any language, without serious confusion.

In surveying this literature, we were impressed by the large number of Japanese articles on aviation medicine. Much more striking, however, was

fact that about thirty Russian journals were represented in the bibliography, embodying a vast and well-co-ordinated literature on the subject—far ahead, incidentally, of that of Japan.

There is a widespread feeling that bibliography is a dull preoccupation reserved for spinsters and old maids of the male sex. Actually, it is far from that, for careful analysis of the literature of any subject reveals trends of research, and in the bibliography under consideration, it has exposed trends and emphasis of far-reaching international significance. The Germans, for example, began publishing papers on the effects of high acceleration in aircraft five years before the flight surgeons of the United Nations had given any general consideration to the problem, and everyone must realize what the dive bomber has meant to the Axis war effort. For better or for worse, the Allies have depended largely on horizontal bombing, but with our fast fighters we are quickly learning the significance of high acceleration, and are studying the modes of counteracting its effects on aircraft personnel.

#### PROBLEM OF ANOXIA

The responsibility of carrying on research in the more academic phases of aviation medicine falls largely to the civilian laboratories, although one looks forward to research institutes within the military services that will continue with active investigative endeavor in times of peace. But in the present war crisis, it is clearly up to the civilian scientists to undertake the long-range problems, and in aviation medicine the most basic of these is a study of the adjustments of the body to anoxia. There are many aspects of the problem as yet imperfectly understood,—individual variations, variations of the individual,—factors that aid the body in making the adaptations, all of which involve fundamental physiological, biochemical and endocrinological research; the aim in view is to increase knowledge of the processes involved and to search out ways of improving human performance in the higher altitude ranges. To use the language of aviation, the basic problem is to raise the aviator's "ceiling." But from the purely academic standpoint, we wish first to extend our knowledge of the processes involved.

In his excellent monographic review on the effects of anoxia in the body, Van Liere<sup>8</sup> gives a broad picture of the manifold changes that occur when the body is exposed to low oxygen partial pressure. In adjusting, for example, to a fall of half an atmosphere, giving an equivalent altitude of 18,000 feet, there is a veritable ionic cataclysm between blood and tissues and renal tubules, accompanied by a shift of the blood pH to the alkali-

line side, with an extensive loss of sodium and chloride ions in the urine. Van Liere, however, makes little attempt to elucidate the important problem of how these ionic shifts are integrated. What organ responds in the first instance to the lowered oxygen partial pressure? From the work of Cannon<sup>9</sup> and of Gellhorn and his collaborators,<sup>10, 11</sup> it is known that the sympathetic system is exquisitely sensitive to anoxia and that many of the adjustments arise from the direct stimulating action of low oxygen tension on the central neurons of the sympathetic system. From the sympathetic comes the reflex mobilization of idle red blood cells from spleen, bone marrow and other reservoirs, and a vast series of vasomotor readjustments designed to improve the circulation of vital organs is brought about, also reflexly, through interaction of the sympathetic and parasympathetic systems. No one, however, appears previously to have suggested that the ionic shifts essential for anoxic acclimatization are likewise mediated through reflex channels. The evidence to date is incomplete, but suggestive, and it turns largely on recent developments bearing on the part played by the adrenocortical hormone in anoxia.

#### Anoxia and Adrenal Cortex

Two papers published by French flight surgeons at the end of the last war suggested that the asthenia that certain aviators developed after repeated missions to high altitudes was due to adrenal insufficiency. Ferry<sup>12</sup> observed urinary retention of nitrogen and alkali, low blood pressure and pathological heart sounds in a group of over-fatigued aviators, and he was led on the basis of these findings to the conclusion just mentioned. The paper of Josué<sup>13</sup> was based on a study of physiological and psychological alterations in fatigued pilots. But since at that time there was no clear distinction between the adrenal medulla and the cortex, the suggestion can remain only of historical interest. More recently, Armstrong and Heim<sup>14</sup> found on exposing rabbits for four hours a day to an atmosphere equivalent to 18,000 feet that, in the early stages, hypertrophy of the adrenal gland resulted and was followed later by degenerative changes in the adrenal cortex. In his well-known book on aviation medicine, Armstrong<sup>15</sup> later pointed out that overfatigued pilots, especially those subjected to many high-altitude missions, developed symptoms strikingly similar to those seen in early Addison's disease.

Sundstroem,<sup>16, 17</sup> whose early studies on the adaptation of man to high altitudes are well known, was led some years ago to study the relation of the adrenal glands to acclimatization

and, independently of Armstrong and Heim, confirmed the existence of adrenal hypertrophy resulting from anoxia; in his monograph about to appear from the University of California Press, he<sup>18</sup> shows that the degree of adrenal hypertrophy can be roughly correlated with the extent to which the oxygen partial pressure is diminished. All animals exposed to diminished atmospheric pressure during the period of acclimatization tend to lose weight. This loss of weight is shared, according to Sundstroem, by all organs of the body except the adrenal cortex (and possibly the kidney); the adrenal hypertrophy is therefore regarded as something specific to the anoxic state. On the basis of the hypertrophy, Sundstroem asked himself whether this might not indicate increased secretion of the glands. He set out to obtain a direct answer to the question in two ways. In the first place, adrenal steroids were extracted from tissues, such as the heart and liver, from control animals at sea level and from groups exposed to the high-altitude ranges; the tissues of the latter animals invariably showed a larger proportion of adrenal steroid than the corresponding tissues in animals at sea level.

More impressive, however, was the study of Giragossintz and Sundstroem,<sup>19</sup> in which it was found that adrenalectomized animals could not survive in the high-altitude ranges and that it took twenty times more crude extract of the adrenal cortex to maintain rats at 20,000 feet than it did at sea level. This clearly suggested that to maintain the body at high altitude increased secretion of adrenocortical extract is essential.

The problem has recently been taken up anew in my laboratory by Langley and Clarke,<sup>20, 21</sup> who have confirmed the fact that adrenal hypertrophy develops in rats exposed to 20,000 feet; and in adrenalectomized animals, they find that at sea level the maintenance dosage for an average adult rat is 0.5 cc. of total extract a day (Wilson), or 0.03 mg. of desoxycorticosterone acetate. At 20,000 feet, a rat on this maintenance dose rapidly loses weight and dies, and Langley and Clarke find that 2 or 3 cc. of total extract is essential at that altitude and that 1 mg. of desoxycorticosterone is required. When acclimatization has taken place, however, after one week at 20,000 feet, the maintenance dose can be reduced to the sea-level amount.

Langley found, as had Gerald Evans,<sup>22, 23</sup> that exposure of a fasting rat to an altitude of 20,000 feet for twenty-four hours causes an elevation of both the blood-sugar and liver-glycogen levels. This suggests that Compound E, the carbohydrate fraction of the adrenocortical secretion, is mobilized in conditions of anoxia. But the desoxycorticosterone fraction appears also to be mobilized, since Langley has found in dogs exposed to an altitude of 20,000 feet

that a marked increase occurs in sodium and chloride and also in potassium excretion. Following adrenalectomy, dogs subjected to anoxia failed to show the sodium and chloride excretion, although potassium loss continued. The failure of the sodium, chloride and carbohydrate adjustments in adrenalectomized animals exposed to anoxia indicates that the presence of adrenal extract is apparently essential to make the bodily adjustments to altitude, and one naturally wishes to know how the adrenal cortex is specifically activated—whether directly by the blood stream, or in some way through the nervous system. Langley,<sup>20</sup> in discussing the question, remarks: "It is possible that the increase in sodium, chloride and urine volume observed in the normal animal exposed to anoxia was brought about by increased excretion of these specific fractions [desoxycorticosterone] of the adrenal cortex. This observation suggests that the adrenal cortex is capable of secreting certain components of the whole extract independently of the others."

The recent important work of Dr. George Thorn,<sup>24</sup> the newly appointed Hersey Professor of Medicine at the Harvard Medical School, has also established in animals that a large increase in sodium, chloride and potassium excretion occurs on exposure to anoxia, and he has found conspicuous nitrogen retention in man under these conditions. Treatment of adrenalectomized animals with the so-called "carbohydrate-regulating" factor caused a striking increase in sodium, chloride and water excretion, but no increase in potassium. Thorn and his collaborators<sup>25-27</sup> have just given an account of the effect on rats, rabbits and dogs of intermittent exposure to altitudes equivalent to 18,000 and 27,000 feet. They have confirmed Armstrong and Heim's<sup>14</sup> observation that adrenal hypertrophy develops in consequence of such repeated exposure in rabbits (and also rats); they have found, moreover, that the adrenalectomized animal fails to survive repeated "flights" to these altitudes, and that their capacity for adjustment can be restored by administration of adrenocortical hormone.

From the studies of Collip<sup>28</sup> and his students, it appears probable that the adrenal cortex is normally activated, not by the blood stream directly, but rather by the adrenotropic hormone of the anterior pituitary. The ingenious work of Uotila<sup>29, 30</sup> indicated that the thyrotropic hormone is under the direct control of nerve centers in the hypothalamus whose axons passed down the pituitary stalk, and that the reaction to cold results from thermal stimulation (via the blood) of the hypothalamic centers. Since the adrenal cortex also plays a large part in the reaction to cold and to anoxia, it is likely that the primary activation of the adrenal cortex comes from the hypothalamus through the adrenotropic hormone. Favoring this is the fact, originally disclosed by Gerald Evans<sup>22</sup> and recently confirmed by Catchpole,<sup>31</sup> that the chronically hypophysectomized rat has

no greater altitude tolerance than the adrenal-ectomized animal

All this brings one to a far clearer concept of the mode of integration of the bodily adjustments to altitude. The part played by the respiratory center in the medulla has long been recognized. Mobilization of red cells and the reflex adjustments of the heart and circulation arise in part from direct stimulation of the chemoreceptors of the carotid body, as well as from the direct effect of low-oxygen tension on the sympathetic system; there appears to be further reflex control, through the centers in the hypothalamus, of the ionic pattern and carbohydrate level of the blood. Undoubtedly, when the complete picture has been put together, the posterior pituitary gland will also be found to play a part in these adjustments through the influence of its antidiuretic hormone on the kidney tubules. This strongly suggests that the bodily adjustments to anoxia are in large measure integrated by the central nervous system.

#### SAFETY IN CRASHES

The military phases of aviation medicine are rigidly practical. General academic research is encouraged at some of the larger bases and institutions, but for the immediate purposes of the war effort a group of practical problems has arisen for which solution is required in a matter of months. Combat fliers, for example, are constantly exposed to rough landings under black-out conditions, or to crash landings when machines are disabled, and the question arises whether mechanical factors for safety, similar to those introduced within the past few years in automotive design, cannot be adapted to aircraft. This raises the question of the factors responsible for injuries, fatal and otherwise, in air crashes. Close study of the large literature on air crashes indicates that impact of the body, especially the head, with some solid part of the aircraft is generally the cause of death or of serious injury, even in minor accidents. When the body or the head strikes something that yields, as when the flier is thrown through a fabric roof or the windshield, the victim generally escapes serious injury. What, then, are the basic factors that govern the degree of injury in such circumstances?

The most significant clues have come from two sources. De Haven's<sup>12</sup> analysis of nonfatal suicidal leaps from high buildings, and a study, for which Denny Brown is largely responsible, of the effects of sudden acceleration on the head.

**Nonfatal suicidal leaps.** In a series of recent papers, De Haven<sup>12-13</sup> has drawn attention to some remarkable cases of suicidal leaps from high buildings that proved not to be fatal. A number

of such cases—in which all data were available concerning the exact distance of the fall, the position of the body during the fall and on landing, and the character of the surface that the body struck—permitted him to draw certain generalizations on the nonfatal leap, the victim generally landed flat on the back or flat on the stomach, so that the long bones or the head was not driven into the trunk. But more interesting is the fact that a slight degree of cushioning of the head, as in landing in a garden plot instead of on a cement sidewalk, prevented concussion and serious injury of other parts. A typical case may be cited<sup>13</sup>.

A twenty-one year-old woman, mentally depressed because of an amorous disappointment, took a room on the tenth floor of a hotel, consumed half a bottle of whiskey, and leapt in her nightdress to the street below—a free fall of 93 feet. She landed squarely on her back in a small garden in which the earth had been freshly turned, her head, back and legs sinking into the earth to a depth of 4 to 6 inches. A hand, which struck the cement border of the garden plot, suffered a fracture to a small bone in the wrist, but except for this and a fractured rib she was uninjured, suffered no concussion, and could walk without assistance. Her height was 5 feet, 7 inches, and her weight 115 pounds.

The important point about this and similar cases is that the head experienced a brief interval of deceleration, instead of an abrupt impact on a rigidly solid object. De Haven calculates that the girl's body was falling at a rate of 73 feet a second (50 miles an hour) at the time of the impact, and that the deceleration distance, which amounted to 4 to 6 inches of garden turf, must have taken place in a small fraction of a second; the rate of deceleration was 166 *g* (1 *g* = 32 feet per second per second). There is a vast difference between being decelerated from 50 miles an hour in 0.001 second and being decelerated in 0.1 or even in 0.01 second. Little attempt has been made so far to measure these brief but vital deceleratory time intervals in relation to injury.

A more complex case occurred several months ago in New York and is mentioned because of the relatively long distance of the fall. A woman leaped from the seventeenth floor, falling 144 feet, and landed in a "steamer-chair" position on a metal ventilator box 24 inches wide, 18 inches high and 10 feet long. The force of her fall, De Haven points out, crushed the structure to a depth of 12 to 18 inches. Both arms and one leg extended beyond the area of the ventilator, with resultant fractures of both bones of both forearms, the left humerus and the left os calcis. The woman remembered falling and landing, but had no marks

Java, India, Africa, the Mediterranean and the North Atlantic sea lanes be given a sense of the importance of the contribution they have rendered, be given a sense of the part that they may still be able to contribute if put back into active service. I am not speaking as a psychiatrist, or even as a practical surgeon, but essentially as a layman. I have, however, had opportunity to survey the literature and have seen hospitals filled with sick men, seriously injured men, of the fighting forces of Britain; I cannot too vigorously emphasize the value of maintaining the morale of the injured man, of allowing him to take part in the care of others more seriously incapacitated than himself, and of giving him opportunity to discuss combat problems with those who have been placed before their injury in military situations similar to his own.

\* \* \*

Expansion of the air corps of both the United States Navy and Army has created an unprecedented need for medical personnel. The Navy within the year expects to complete training of more than 1000 air medical officers including several hundred flight surgeons, and Colonel David Grant, Air Surgeon of the Army, authorizes me to say that the Army Air Forces have now in service some 2300 medical officers and that an expansion is expected within the year to bring a total of 19,000 flight surgeons and aviation medical officers. If this demand is filled, it would alone absorb all the graduates of Class A medical schools in the United States during the past three years.

This war is probably more challenging to the physician than any other conflict in the world's history. Those who serve, especially those who serve the air forces, must have special knowledge; they must be cognizant of this, cognizant also of the part that they can play in maintaining air supremacy, and of re-establishing the right of free men to live in peace.

VITAMIN B<sub>1</sub> AND ENDURANCE\*

PETER V. KARPOVICH, M.D.,† AND NATHAN MILLMAN, M.Sc.‡

SPRINGFIELD, MASSACHUSETTS

RECENT reports<sup>1</sup> have indicated that the administration of vitamin B<sub>1</sub> may increase muscular endurance in subjects on a diet deficient in that vitamin. This effect is explained on the basis of the role of vitamin B<sub>1</sub> as an oxidative catalyst employed in the chemical process involved in muscular contraction. For this reason, men engaged in hard muscular work use more vitamin B<sub>1</sub> than those in sedentary occupations, and the amount suggested by investigators for workingmen and athletes is more than 300 international units daily. Yet Stiebeling and Phippard<sup>2</sup> report that a large number of people in the United States live on a diet poor in this vitamin.

The possibility of increasing human stamina and endurance, coupled with a fear of a probable lack of the vitamin, has been impressed on the public mind, and the use of synthetic vitamin B<sub>1</sub> has become widespread. It is employed not only in cases in which a definite vitamin deficiency has been found but also, in a more general way, as insurance against a possible lack of it. Tablets including thiamin chloride are supplied free in some industries, college athletes are given it, and even professional baseball players must take it to remain in the good graces of the management.

Recognizing the importance of vitamin B<sub>1</sub> and its strikingly beneficial effect in patients whose diet has been deficient in thiamin content, we questioned whether an excess of vitamin B<sub>1</sub> could increase the capacity of the human organism for work. At various colleges where either "shotgun prescriptions" including vitamin B<sub>1</sub> or this vitamin alone was being given to varsity athletes, no striking and convincing (at least for outsiders) results were obtained. At Springfield College, Coach Charles Silva had been giving vitamin B complex, but no appreciable effect on the performance in swimming could be detected. The weakness in most of these "experiments" lies in the fact that they lacked controls. Usually, every member of the team received the same dose, and quantitative measures of performance were often impossible. How, for example, can one evaluate the effect of a certain vitamin on basketball players, football players and so forth? It is only when the amount of energy used can be measured, as

in track running or swimming, that the tests become objective.

McCormick,<sup>3</sup> who attempted to improve endurance by giving his subjects a daily dose of 5 mg of thiamin chloride in tablet form, used two tests: breath holding and arm holding. After one week of administration of vitamin B<sub>1</sub>, he noticed definite improvement as measured by these tests. Since, in our judgment, McCormick's appraisal of the vitamin intake of his subjects was not convincing, and the results of the tests were not indicative of the vitamin effect, we decided to repeat his experiments.

**Arm-holding test.** Sixty-nine subjects, all of college age, were tested for the time they were able to hold their arms horizontally. For convenience, these men were divided into three groups (Table 1) in the first group, who were simply

TABLE 1 Summary of Preliminary Arm Holding Tests

ARM HOLDING TIME min	NO PEP TALK	PEP TALK	EMPHATIC PEP TALK

30 to 119	2	2	6
120 to 190	2	2	6
260	—	—	1
Totals	17	23	29

told to hold their arms outstretched as long as possible, the holding time ranged from 6 to 108 minutes, in the second group, who were given a "pep talk" with a reference to McCormick's record (which was erroneously announced as 135 minutes and was actually 145 minutes), the range of endurance varied from 8 to 135 minutes, in the third group, who were tested two days after the first two groups and, naturally, had been talking about the "remarkable" feat of holding the arms outstretched for 135 minutes, an especially emphatic "pep talk" was given and the range varied from 9 to 260 minutes.

Forty-one of the 50 men whose arm holding times were less than 30 minutes were given either 5 mg of thiamin hydrochloride a day or a placebo (5 mg of lactose).<sup>§</sup>

A week later, the second test was given, the range varying from 5 to 77 minutes in the group who did not receive the vitamin, and from 7 to

79 minutes in the men who did (Table 2). In the latter, 8 out of 16 improved, and in the former, 12 out of 25.

Of particular interest is the fact that some of the subjects who were given the preliminary test were on a high vitamin B<sub>1</sub> diet, and some were on a low diet. To the first group belonged the varsity swimmers, and to the second some of the wrestlers who were trying to lose weight. Of the 4 swimmers, 1 could not hold his arms out-

The arm-holding test has been used by other investigators<sup>4, 5</sup> to detect the changes in endurance due to various modifications of the diet. In view of the evidence here presented, the reliability of this test as an indication of muscular endurance should be seriously questioned. Persons who are easily affected by suggestion, or even by auto-suggestion, are apt to give a better performance in this test.

*The breath-holding test.* This is one of the routine class tests given at Springfield College in a course of instruction in the physiology of exercise. During hundreds of tests, it has been observed that the psychologic factors greatly influence the time of breath holding. Nevertheless, we used a group of 20 men for this experiment. They were given two breath-holding tests in succession, and then half the subjects were put on a diet containing 5 mg. of thiamin chloride a day for a week, and half on one containing 5 mg. of lactose a day. No effect of vitamin B<sub>1</sub> on breath-holding ability was observed.

CONCLUSIONS

Vitamin B<sub>1</sub> deficiency in apparently normal college students cannot be discovered by means of either the arm-holding or the breath-holding test.

These tests may be greatly affected by psychologic factors, and are therefore not reliable indications of the degree of muscular endurance.

stretched for more than 10 minutes, and 2 of the others, for more than 60 minutes. Of the 2 wrestlers, one held the position for 161 minutes, and the other for 260 minutes (4 hours and 20 minutes).

These tests showed either that all the men had a sufficient amount of vitamin B<sub>1</sub>, which was questionable in the wrestlers, or that arm holding cannot be used as a test for the effect of the vitamin in apparently normal people, or for vitamin B<sub>1</sub> at all, because the test is definitely affected by psychologic factors, such as a "pep talk" and the competitive elements involved.

## KELOIDS AND THEIR TREATMENT\*

LOUIS H. NASON, M.D.†

BOSTON

**K**ELOIDS may be defined as an exaggerated growth of scar tissue. In this exaggeration, they appear to defy to some extent the normal rules of growth, and have accordingly been considered a bridge or link between normal reparative processes and actual neoplastic changes. However, unlike neoplastic growths, the keloid process is initiated from normal fibroblastic cells solely by trauma. These cells produce the keloid by carrying on their normal function—although to an exaggerated degree. This exaggeration continues even after excision, and in fact, the tendency to recur is the most characteristic feature of the growths. Were this not so, keloids would cease to be a problem.

In their growth, keloids become thicker and heavier and actually extend out into adjacent normal skin, well beyond the border of the original injury. This quality of extending beyond the site of the original injury is a pathognomonic feature of keloids and helps differentiate them from hypertrophic heaped-up scars or cicatrices, which develop at the site of suppurative or the site of previous loss of tissue, are limited entirely to the areas involved by suppuration or trauma, and gradually shrink and become less conspicuous. Keloids always project above the level of the surrounding skin, but extend very little, if at all, into the underlying subcutaneous tissue. In fact, in secondary abdominal operations involving the excision of a keloid occurring in a previous incision, relatively little scar tissue may be encountered in the subcutaneous fat, although the skin keloid may be very heavy.

## ETIOLOGIC FACTORS

Trauma is always the precipitating etiologic factor in the production of keloids. Keloids probably never occur without the preliminary destruction of cells by some form of physical or chemical violence. However, only certain persons consistently develop keloids after moderate trauma. This tendency indicates some sort of fibroblastic diathesis, varying in intensity among races and individuals. Furthermore, the sensitivity of the fibroblasts to substances provoking proliferation and growth may change as the patient gets older and as the rate of growth and metabolism alters. This accounts for the relative scar-

city of keloids beyond the age of fifty. Indeed, it is very rare in the aged, whereas it is rather frequent in the young. In a survey of 50 cases of appendectomy for chronic appendicitis in children between the ages of five and fifteen years, various degrees of keloids were noted in 28 cases—a high percentage.

There are also local influencing factors. Keloids occur only rarely on the face, forehead, hands and feet, front of the neck, axilla, inguinal region, anal region and perineum, whereas they are common around the ears, sides and back of the neck, abdomen and chest (particularly in women). Keloids seldom, if ever, occur in incisions placed in natural flexion creases, although they may occur in incisions or scars running across flexion creases. The only explanation for this phenomenon seems to be the manner in which tension is applied to different areas in the body. It will be noted that in those regions in which keloids seldom occur, the skin and underlying tissues are subject to constantly changing degrees of tension and stress. These areas are very often moved and shifted in the course of ordinary activity. There is a considerable amount of constantly changing stress and strain in the flexion creases and in the perianal and perineal regions. On the contrary, where keloids occur frequently, the skin is under the normal degree of tension but remains almost constantly so with relatively little motion and change. In areas where there is no skin tension whatever,—as in the scrotum and in the upper eyelids,—keloids do not occur. One other interesting phenomenon is the rarity of keloids in the hairy regions of the body. All these local factors are of primary importance in the selection of sites for incisions and in the prevention and treatment of keloids.

## TREATMENT

The treatments advocated for keloids have been legion. If one is shocked at the lack of rationale of some of them, one may at least admire their ingenuity. Lesieur<sup>1</sup> injected oil of creosote, and Smyth<sup>2</sup> used formalin. Attempts at digestion of the keloid were made by Ahlsvede,<sup>3</sup> who used a mixture of pepsin and hydrochloric acid. Hoffman,<sup>4</sup> in his paper advocating radiation as the treatment of choice, lists twelve methods of treatment collected from the literature, but many more can be gathered without difficulty. These vary

\*From the Plastic Clinic, Beth Israel Hospital.  
†Instructor in surgery, Harvard Medical School; assistant in surgery, Beth Israel Hospital.

from Sheehan's<sup>5</sup> "capillary" drainage to iodine ionization, advocated by Grain.<sup>6</sup> Cannon<sup>7</sup> painted the lesions with trichloroacetic acid to thin out the keratotic layers and then subjected the lesions to roentgen radiation. This author also recommends desiccation, preceded and followed by x-ray treatment. Unna<sup>8</sup> reported a patient cured of a keloid by the application of pressure renewed weekly for three months.

No one treatment produces good results in all keloids, but considerable success may be attained consistently if all factors in each case are carefully

orthodox ones. The suture material should be as fine as possible—preferably a No. 000000 dermal plastic suture. A cutting-edge needle is far less traumatizing than a round needle. If the wound is not under tension, the sutures should be removed in forty-eight to seventy-two hours. Very accurate approximation, of course, needs no further emphasis.

Constant excessive tension must be released either as a preliminary to further surgery or radiation or in the process of excision. If a keloid is excised and the edges approximated under

FIGURE 1. *The Z Plastic.*

*A—the keloid has been excised, and two parallel incisions made, defining two flaps (a and b); B—the flaps are transposed and sutured; note that the lines of tension are rotated through 90°.*

considered. A keloid in a given patient is not a stereotyped condition. The very realization that one is dealing with a lesion that occurs because of a specific type of diathesis and may be influenced by local factors will in itself serve to orient one in the consideration of the proper treatment. Certain essential principles must be adhered to. These are the avoidance of further trauma, the release of constant excessive tension, the application of pressure, and the careful use of surgery in addition to radiation.

Rough handling, vigorous massage, careless surgery and the application of traction serve to aggravate or reproduce the keloid. Whatever procedure is carried out, it is well to remember that trauma produced the lesion to begin with, and that by no stretch of the imagination can one believe that trauma can also effect a cure. Nowhere in the realm of surgery does a satisfactory end result depend so much on scrupulous, atraumatic technique as in the surgical removal of keloids. The use of a sharp knife, fine-pointed forceps and sharp, cutting-edge, atraumatic needles is necessary. The exact type of suture material or stitch does not matter. Subcuticular sutures are apt to give poorer approximation and more reaction than the more

exactly the same conditions of tension as previously existed, the keloid will certainly recur. It is for this reason that simple excision is inadequate. The essential fact is that the direction of established stresses should be changed if possible. A Z plastic is of invaluable aid in such a situation (Fig. 1). This produces a rotation of the vertical portion of the Z to the horizontal, and rotates the direction of the maximum tissue tension 90°. Simple excision may be carried out successfully on the abdomen, the upper extremity and the neck.

Subsequent tension may be avoided by judicious choice of flap plastics in place of free skin grafts. Free grafts of all sorts tend to contract and pull the surrounding tissues around them. When a pedicle graft may be used in place of simple suture of skin graft, it is preferable. Releasing incisions are very useful provided they do not jeopardize the cosmetic result. If they can be placed in a natural crease or within a hairline, they serve as a valuable adjunct. Satisfactory results may be obtained in the excision of a keloid from the back of the neck by the use of a parallel releasing incision placed 3 or 4 cm. higher up in the scalp itself. The combination of the releasing incision and the flap is illustrated by a type of plastic very

suitable for keloids over the broad surfaces of the body, such as the chest and back (Fig. 2). This consists of excision of the keloid and then the making of a V-shaped incision a suitable distance from the defect so that a flap may be raised and transplanted to obliterate the original defect. The V-shaped defect in the new incision is then closed in a Y-shaped approximation.

The use of radiation for the treatment or prevention of recurrences of keloids is by no means so logical or consistently successful as some reports indicate. The old, well-developed keloids are

utilized with comfort. The simplest method is to fashion a throat stick, a piece of dental impression compound or a piece of heavy felt to conform to the shape of the keloid. This mold is then strapped tightly to the keloid. Strappings should be changed weekly. If adequate pressure is applied, a remarkable change is noted after the first week, but if the pressure is not continued, the keloid quickly resumes its original prominence. The strapping, therefore, should be renewed weekly, with no interruption for at least six to eight weeks, and pos-

FIGURE 2. *The V-Y Plastic.*

*A—the keloid has been excised, and a V-shaped incision made, parallel to the long axis; B—the original defect is closed in a straight line, and the V-shaped defect as a Y; such closure produces no tension.*

extremely resistant; the younger ones respond well to radiation. Hence, if radiation is to be employed, well-developed keloids should first be excised, so that they may be supplanted by a young keloid. The best results reported are in those series in which radiation, from three to five days postoperatively, is given after surgical excision. It is assumed that at that time the young proliferating fibroblasts are most sensitive to radiation. In fact, radiation delayed a few days after excision yields better results than radiation given into the open wound at the time of or within twenty-four hours of operation.

Excision of the keloid, in addition to any plastic procedure necessary to relieve tension, followed by radiation in moderate dosage from three to five days postoperatively is what I believe to be the method of choice in most cases.

The use of pressure, when applicable, may yield excellent results with no risk of recurrence. It is not rare to note keloid formation in the lower half of a low abdominal scar, whereas in the upper portion—where the imprint of the elastic of an undergarment or belt may be seen—no keloid is present. The ischemia produced by the pressure arrests overproduction of scar tissue. Slight but constant pressure may be applied to some portions of the body over long periods. Over the extremities, the abdomen and the shoulders, pressure by means of adhesive strapping may be

sibly longer. This method is particularly applicable to young keloids, which are more vascular and contain less collagenous material than the old ones. The local anemia induced by the pressure has more effect on the more vascular lesions. Obviously, pressure is not applicable to the face, the neck, the front of the chest and parts of the back. Pressure may be utilized in the prevention of recurrences by the simple expedient of keeping the incision covered with a strip of adhesive plaster for many weeks. The light, even pressure of the adhesive results in a much smoother, softer scar, with practically no elevation above the skin.

If keloids recur, the average time of recurrence is two or three weeks. Evidence of return may even be noted within two weeks. However, if keloids do not recur within six to eight weeks, one may consider subsequent recurrence extremely remote.

## RESULTS

The following results were obtained from observations on fifty-one keloids in 49 patients. The cases were grouped according to the method of treatment, as follows: excision and reapproximation; radiation; excision and radiation; and pressure. Table 1 indicates the results obtained. For the purposes of tabulation, a result was considered satisfactory when the keloid was not longer present, or when it was strikingly improved. A fair

result was indicated by definite, but partial, improvement, and an unsatisfactory result by a case in which the keloid remained unchanged, recurred or became more marked.

SUMMARY AND CONCLUSIONS

The exact etiologic factors in the production of keloids are not known, but there is sufficient

TABLE 1. Results of Four Methods of Treatment.

evidence to indicate wide variations in racial and individual susceptibility. In addition, certain local factors, particularly the manner in which local skin tension is applied, may be shown to have a determining influence in the occurrence of keloids. Areas in which skin tension is constant are apter to be the site of keloids, whereas in areas where

there are frequent changes in tension of the skin, — such as the creases, — keloids rarely occur. In these areas, keloids do occur if the original scar is sufficiently extensive or if it extends across the normal lines of tension.

Treatment consists in the avoidance of further trauma, the release of constant and excessive tension, the careful use of surgery, in addition to radiation, and, rarely, the use of pressure alone. Pressure may also be employed to prevent recurrence after excision. When pressure cannot be utilized, the treatment of choice consists in excision of the keloid, in addition to any plastic procedure necessary to relieve tension, followed by radiation in moderate dosage beginning from three to five days postoperatively.

MEDICAL PROGRESS

OTOLOGY: THE TREATMENT OF DEAFNESS IN THE LIGHT OF RECENT ANIMAL EXPERIMENTATION\*

M. H. LURIE, M.D.†

BOSTON

TO treat the deaf successfully has been the ambition of all otolaryngologists. Unfortunately, the otologist is immediately on the defensive when the patient announces that he is deaf. The mental sigh of relief when large plugs of cerumen are found is almost audible, for here is something to be done that will give relief. As for the other types of deafness, except for certain conditions such as the acute suppurative and the secretory ear, the otologist, after establishing the diagnosis, considers the case hopeless and subconsciously prays that the patient will not return.

Reprints of articles in this series are not available for distribution, but the articles will be published in book form. The current volume is *Medical Progress Annual, 1940* (Springfield, Illinois: Charles C Thomas Company, 1941. \$4.00).  
\*Read by invitation at a meeting of the Pacific Coast Oto-Ophthalmological Society, Los Angeles, California, May 26, 1941.  
From the Departments of Otolaryngology, Harvard Medical School, and the Mosher Laboratory, Massachusetts Eye and Ear Infirmary.  
†Assistant professor of otology, Harvard Medical School; surgeon in otolaryngology, Massachusetts Eye and Ear Infirmary; consulting otolaryngologist, Massachusetts General Hospital.

This defeatist point of view is not due to lack of knowledge of methods of treatment used at present, but to a failure to realize that many types of deafness can be helped even though the condition cannot be cured. To approach this subject intelligently, one must have an understanding of the present conception of how people hear.

Hearing is not a function of the middle or inner ear alone but is in reality a phenomenon of the brain resulting from the interpretation of nerve impulses coming to it from the sense organ for hearing, the organ of Corti. The basic requirements for hearing are a normal sense organ to receive the sound waves and a normal brain to interpret the messages received from the sense organ. The middle ear and its structures are aids and refinements for acute hearing, but are not essential to hearing, for which other apparatus can be substituted in certain types of deafness.

The statement that a normal brain is essential for hearing may raise doubts in many minds, but I should like to point out that all animals of the mammalian group (man is one) hear in the same manner but that the interpretation of the sense-organ stimulation varies tremendously with the development of the brain. The newborn infant does not hear until he has learned to interpret the stimuli received, and as the interpretative power of the child increases so does his hearing, for it is from this ability to interpret and repeat the sounds heard that speech and its accessories, reading and writing, have developed.

The membranous labyrinth, with its vestibular and cochlear sense organs, is well known and requires no detailed description. I should like to draw attention to the way these two sense organs work. They both depend on movements of fluid to stimulate them. The vestibular apparatus requires movement of the endolymph—that is, movement of the fluid inside the membranous vestibular structures. The cochlear mechanism depends on movement of the perilymph, which is outside the membranous cochlea. Thus, the vestibular portion can be called the endolymphatic system of the membranous labyrinth. The cochlear portion can be called the perilymphatic system of the membranous labyrinth. This distinction is important and is more fully discussed below.

The organ of Corti is the sense organ for hearing. It consists of specialized neuroepithelial hair cells, which are probably stimulated by movement of the basilar membrane. The membranous cochlea is so arranged that the stimulation is through the perilymph, as one can easily see when examining the relation of the membranous cochlea (scala media) to the perilymphatic spaces, the scala vestibuli and tympani. The organ of Corti is not concerned in the question of how this movement of the perilymph is obtained, but once it is produced in sufficient strength to cause movement, it responds and the resulting sensation is hearing.

Thus, deafness divides itself into two types. The first is that in which the organ of Corti itself is involved: the hair cells may degenerate, and as a result, there is an inability of the organ of Corti to respond to the fluid-pressure changes, even though these pressures are made in a normal manner. This lack of response has been called "nerve deafness," because it was thought to be a degeneration of the cochlear nerve; "variable deafness," because there are a great many types of hearing loss with this condition; and "perception deafness," because the deafness is a result of failure of the sense organ to respond to the stimuli sent to it. These three terms indicate the same type of deafness. In the second type, the fluid-

pressure changes are prevented, or made more difficult to produce, in the perilymph. The organ of Corti is normal, but with lack of stimulation, there is no response. This type of deafness, which is due to the inability of the external air-pressure changes or air sound waves to be transmitted to the perilymph, is therefore called "transmission deafness" or "middle-ear deafness," for these structures are involved.

The middle ear and its structures have to do with the changing of air-wave pressures into fluid-wave pressures. Anything interfering with this function results in a loss of hearing. The plugging of the external ear by wax or debris is the simplest type to remedy. Pathologic conditions of the middle-ear structures, such as fusion of the malleus and incus or adhesions around the ossicles, which prevent them from moving freely, the thickened and retracted drum, perforations of the drum, chronic suppuration and acute suppuration of the middle ear, all cause deafness for air-borne sounds, for they interfere with their transmission. Otosclerosis acts in a similar manner, that is, by an interference with air-borne sounds. Sound waves transmitted by the vibration of the bone structures surrounding the membranous cochlea are not interfered with, and the normal organ of Corti responds readily to them.

Thus, it is the duty of the otologist to use all the knowledge he has to overcome this transmission difficulty. Mechanical means, such as the hearing trumpet and the fan that is held by the teeth, to conduct sound waves to the cochlea have been employed. The new hearing aids are of great benefit to many. Most of these patients can be helped if the otologist will take time and effort to find the method to be used. A great many patients with large posterior perforations are helped by the application of a paper drum, which can be made out of patipar paper, is waterproof and stays in place very readily. One can be pleasantly surprised at the amount of hearing improvement obtained by the use of a paper drum. The making of absorbent-cotton drums should be known to all, and many patients have used them for years.

One of the finest appliances for patients with a posterior perforation or absence of the drum or ossicles, and even in those who have had radical mastoid operations, is the Pohlman<sup>1</sup> apparatus. This device has proved very satisfactory, even in cases that are discharging and in dry cavities. The principle on which it is based is the replacing of the former normal human transmitting apparatus with one similar to the bird's middle ear. This appliance, when in place, can be worn for long periods. Patients have had them in as

long as eight or nine months and have heard remarkably well with them.

All the methods described above depend for their good results on the ability of the apparatus used to change the air-borne sounds into fluid waves, and a normal or almost normal organ of Corti to respond to the stimulation. It would be unwise to expect these aids to enable a patient with a diseased or degenerated organ of Corti to hear better, for no matter how good the transmission, there is no sense organ to respond.

Thus, the fenestration operations of Holmgren, Sourdille and Lempert are sound from this point of view, and they should work so long as the perilymph can be stimulated by air-pressure changes, that is, by sound waves. It must be perilymph stimulation and not endolymph stimulation. Stimulation from endolymph-pressure changes results in vestibular responses such as dizziness and nystagmus. The fact that a case of fistulization responds to pressure changes of the endolymph is not necessarily an indication that the perilymph is also responding to air-pressure changes. The difficulty with the fenestration operation is not that it will not work, but in keeping the fistula in such a state that the perilymph will continue to respond to sound waves. New-bone formation, fibrous bands and even a complete blocking of the perilymphatic spaces around the fistula will nullify all the efforts of the operation. The fistula operation is a definite step forward in the attempt to cure transmission deafness. Whether such deafness is due to otosclerosis or middle-ear deafness is immaterial. The main question to be kept in mind with this operation is, Has the patient a normal or nearly normal organ of Corti to respond to the resulting stimulation? If not, the operation should not be done.

The present technical difficulties will be overcome in the near future. Only time will tell if the regeneration of bone or the other mishaps that have occurred in this operation can be prevented. Thus, it does not behoove one to take sides regarding this operation, but to allow time and further experimentation to tell the story. Again, one must remember that the new technics are not easily acquired. No otologist at the present time should expect to get results in his early operations. In fact, it should be emphasized that it is an operation for the younger generation of otologists to attempt and then only after an arduous and thorough training in its technics and indications. There is no doubt that the fenestration operation will have a definite place in the otology of the future.

Middle-ear or transmission deafness, except otosclerosis, results from neglect of mild middle-ear disease caused by the common cold, with its blocked eustachian tube. There is a great deal of literature on this subject, but many otologists

still do not realize that it is their duty to warn the public and to emphasize the fact that a great deal of middle-ear deafness can be prevented. The children with the neglected mild catarrhal or secretory ears are the future middle-ear deaf persons of adult life.

Middle-ear deafness is a problem that has been attacked in a great many ways, for its chief fundamental pathology is the prevention of sound waves reaching the organ of Corti, and this can be overcome. The great challenge to the otologist is nerve deafness of the acquired or inherited type. Before undertaking the treatment of this disorder, one must understand it. Is it nerve degeneration or degeneration of the sense organ itself? Nerve deafness can theoretically occur in one of three ways: by destruction of the central nerve pathways for auditory stimuli, such as hemorrhage in the brain, intracranial tumors and arteriosclerosis with degeneration of the auditory cortex; by degeneration of the cochlear nerve secondary to meningitis, as in cerebrospinal meningitis, influenzal meningitis, syphilis, acoustic neuromas in the external auditory meatus and toxic conditions that may attack the nerve endings; and by degeneration of the sense organ itself—that is, degeneration of the internal and external hair cells, accompanied by secondary degeneration of the cochlear nerve.

In nerve deafness, one characteristic stands out. The patient can hear the sounds but cannot make the words out accurately. He is always complaining that people do not articulate properly. They mumble, and as a result he cannot hear. What does he miss? He misses the very fine, high sounds of small intensity. These high-frequency sounds make the difference between words that have similar vowels but different consonants. If the intensity of the spoken words is increased, the patient has less difficulty in distinguishing them. He has trouble hearing people on the telephone and can never hear everyone at the dinner table or in a room filled with people talking at the same time. Noisy places bother him. He hears best when conversing with a single person.

There is no evidence from these people that their brains cannot interpret, but there is an indication that the auditory impulses received by the brain from the organ of Corti are the result of sound waves not received accurately. If the cochlear nerve is at fault, one would expect complete blocking off of the impulses from the organ of Corti, with a resulting complete loss of hearing for the area involved. This does happen in some cases, with complete loss of tones above 5000 but with normal responses below these frequencies. Others may have definite islands of deafness. But the majority of nerve-deaf people hear all tones from 64 to 8000 cycles per second when they are made

loud enough; this shows that the nerve itself is not primarily responsible for this type of deafness.

From experimental studies on animals and human beings, the evidence at present is that the end organ itself is primarily the cause of nerve or perception deafness.<sup>2,3</sup> The following data were obtained from animals, for it is from this material that the treatment of nerve deafness can be evaluated.

It has been known for years that people exposed to loud sounds for long periods become deaf, and the type of deafness that develops is a nerve deafness. It has been called blacksmiths' deafness, boilermakers' deafness, riveters' deafness and, recently, aviators' deafness. Animal experimentation definitely shows that this type of deafness is the result of degeneration of the organ of Corti, the external hair cells go first, and then the internal hair cells. The testing of the electrical response of the organ of Corti of experimental animals showed a typical loss of function similar to that of the nerve deaf person. This was confirmed by the fact that the person subjecting these animals to the sounds also lost his hearing in a similar manner. Exposure of human subjects to extremely loud sounds for short periods gave similar results. Fortunately, the human organ of Corti recovered from these experimental exposures, but there is no question that if the exposures were repeated more frequently and for longer periods, there would be a marked and permanent loss of hearing owing to degeneration of the hair cells.<sup>3</sup>

Chemical poisoning of guinea pigs in which prolonged doses of quinine were given also resulted in degeneration of the hair cells. Animals were found that were deaf secondary to disease of unknown origin. They also had degeneration of the external hair cells, and some degeneration of the internal hair cells. In the first group of animals (deaf as result of disease), there was also degeneration of the cochlear nerve. In the first two groups, the cochlear nerve gave no evidence of gross degeneration.<sup>3</sup>

This experimental work demonstrates that the nerve-deaf person has a degeneration of the external hair cells scattered over a large area of the organ of Corti. As a result, he has lost his ability to interpret the fine and weak sounds of high frequency, and this loss causes his deafness. If the sounds are made louder, his interpretation is better, because internal hairs begin to respond to the stimuli and the hearing is improved.<sup>2</sup>

The nerve deaf person first appears for treatment when he has already lost between 20 and 40 decibels of hearing. The reason is that the deafness comes on gradually and over a long period. It may be years before he notices that he no longer can hear as other people do. To treat this patient

with the expectation of restoring hearing is futile. To treat with the expectation or hope of preventing further loss or even slight improvement is justifiable.

A number of factors causing degeneration of the hair cells may be grouped as follows. Toxic poisons such as alcohol to excess, tobacco, quinine and salicylic acid compounds, chronic infections, with toxic absorption affecting the end-organ apparatus; endocrine disturbances; and certain diseases, such as pneumonia, influenza, mumps, syphilis and meningitis, attacking either the nerve or the organ of Corti. Any one or all in various combinations can cause nerve deafness.

One must remember, in treating these patients, that no cure can be promised or expected. In the majority of cases, nothing can be done except to try to prevent further damage to the organ of Corti. Degenerated hair cells cannot be restored. All one can do is to try to prevent further degeneration, and even this may be impossible. It is true that every now and then one seems to improve the hearing in some of the nerve deaf people. This is usually the result of improving the general health of the patient or of treating the endocrine defect if it can be found. In all cases, one should build up the general physical condition of the patient. Vitamins or estrogenic substances, it must be understood, are not cures for deafness. They cannot restore degenerated or absorbed hair cells and nerve ganglia that are gone.

Tinnitus that is possibly due to nerve irritation may be temporarily relieved by the use of the vitamin B complex in large doses. Selfridge<sup>4</sup> and others have reported their results. The experimental work with vitamins, as reported by Melinby<sup>5</sup> and Covell,<sup>6,7</sup> was done on very young and rapidly growing animals. The experiments performed on adult animals have not, as yet, produced the same results. It is not rational to expect that vitamins will restore to normal function a sense organ that for years has been degenerating because of disease or lack of vitamins. The majority of people with this complaint are over thirty years of age.

A great many of the nerve-deaf patients also have middle ear conditions that can be helped, and it is in the treatment of such conditions that the best results have been obtained, not in the actual restoring of the organ of Corti, but in the improvement of the mechanism that has to do with transmission of sound, so that the patient can use his sense organ to its greatest efficiency.

Thyroid has also been used as a cure for deafness. The only cases I have found that were helped were definite hypothyroid cases in which the loss of hearing was due to the slow cerebration of

the patient rather than to a true loss of sense-organ cells.

There is also a group of patients that inherit deafness, not the congenitally deaf, but persons who begin to lose hearing at definite ages, from puberty to forty-five years; their histories indicate that members of their families have sustained the same loss. Nothing can be done for them. It is interesting that animals also have this tendency to inherit deafness. In these animals, the deafness is primarily due to a degeneration of the hair cells of the organ of Corti.<sup>8</sup> Otosclerosis is considered an inherited disease in which there is first a middle-ear and later a nerve deafness.

In recent experimental work on human beings, it has been demonstrated that tinnitus of definite pitch is due to irritation of the organ of Corti itself. The pitch of the tinnitus could be determined on either side of the traumatic lesion caused. Further proof of the organ of Corti as the cause of tinnitus with definite pitch was found in experiments on human beings in which the cochlea was stimulated electrically.<sup>9</sup> It was impossible to stimulate the cochlear nerve and obtain definite pitch. The sound reported on stimulation of the cochlear nerve was a general buzzing or hissing noise, but no accurate placing of pitch was possible. That the nerve was being stimulated was proved by the fact that there was also response of the vestibular nerve, which was being stimulated at the same time.

In a number of cases, in which the hearing loss was due to labyrinthitis, one could not get responses for tones except where the organ of Corti was present and definite tone islands were found. Patients with middle-ear deafness due to large perforations, ossiculectomy or radical mastoid operations responded to tones up and down the range very accurately, and could match the tone with air-borne sounds sent to the other ear. These experiments on human subjects have definitely shown that stimulation of the nerve itself cannot enable the patient to hear. The sense organ must be present.

In studies being done on traumatic deafness, it has been possible to demonstrate trauma to the organ of Corti. In one of these experiments, it took several days for the subject's hearing to come back to normal. Studies on animals showed similar results and indicate that disorganization of the hair cells and not the nerve is the primary cause of traumatic deafness.<sup>2, 3</sup>

One must view with a great deal of caution all claims for curing deafness that depend on systemic treatment. I know of no drugs or methods of treatment that will restore hair cells once they have degenerated. Again, prevention and not attempt at cure is the only hope.

The organ of Corti is the last of the special senses to be developed. It is a most sensitive sense organ, and is easily affected by a great many factors, such as disease, chemical poisons and trauma. No other sense organ in the body reacts so quickly to physical disturbances. In fact, in some ways, the cochlea is an indication not only of physical well-being but also of actual age in its relation to the body structures. Thus, at the present time, methods of treating the nerve-deaf person are limited to the removal of poisons, either chemical or toxic, and to the improvement of the general health of the patient.

\* \* \*

It should be emphasized that one can and should do more to help the patients with middle-ear deafness. It takes time, and progress may be slow, but with hearing appliances and with the future possibilities of the fenestration operation one should be more willing to undertake the treatment of these cases.

In nerve deafness, the general physical well-being of the patient should be raised to as high a level as possible. Vitamins and other drugs that are necessary to bring about this condition should be used. Foci of infection causing toxic absorption should be removed. Toxic substances, such as tobacco, alcohol and drugs, should be completely eliminated; partial discontinuance is of no benefit. The results will not be cures, but in all probability, healthier persons who will be able to use to the utmost the hearing that is left.

In many ways, man by his inventions has caused a great deal of deafness. Nature makes few noises that are capable of causing deafness. Man has made many, such as airplanes, riveting machines, explosives, tanks and machinery. One must appeal to the acoustical engineer to reduce, so far as possible, the man-made noises that are causing this delicate and very sensitive apparatus of hearing, the organ of Corti, to degenerate.

## CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTE-MORTEM AND POST-MORTEM RECORDS AS USED  
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

### CASE 28221

#### PRESENTATION OF CASE

A fifty-eight-year-old housewife was admitted to the hospital because of abdominal pain.

In the seven weeks preceding entry, the patient had three episodes of pain and distress in the right upper abdomen associated with nausea and vomiting. Each attack came on rapidly at about three o'clock in the morning following a meal that included "rich foods." Each attack lasted about a day and left the patient feeling very weak. The pain was not cramping and did not radiate. There were no chills, fever or jaundice. The vomitus was never bloody or like coffee grounds. Fourteen hours before entry, the patient was awakened by severe, steady pain in the right upper abdomen and epigastrium. She felt nauseated, and vomited. There was much abdominal distention, some of which was relieved by the passage of gas by rectum. The abdominal pain continued unabated, and at the time of entry there was some pain in the right shoulder. On the morning of entry, the patient had a chill. The bowel movement on the day before the attack was "darker" than usual, although not bloody or tarry. The patient was usually constipated.

Twenty-five years before entry, she had an appendectomy. Twelve years later, she had several attacks of fainting and coughing, with slight hematemesis. A physician took roentgenograms and told the patient that she had "ulcers." She went on a Sippy diet and had no further complaints except for intolerance to fatty foods.

On admission, the patient appeared ill and pale. The heart was within upper limits of normal size. The lungs seemed clear. Deep respiration was painful. The abdomen was slightly distended, without apparent peristalsis. There was tenderness without spasm throughout the abdomen centering in the right upper quadrant. No masses were palpable.

The blood pressure was 122 systolic, 60 diastolic. The temperature was 99.5°F., the pulse 80, and the respirations 18.

Examination of the blood showed a white-cell count of 19,600. The blood Hinton reaction was negative. The urine was normal.

On the first hospital day, an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR. RICHARD H. SWEET: Attacks of pain such as this patient had coming on at three o'clock in the morning after an evening meal of rich foods are likely to be caused by gallstones.

The temperature of 99.5°F., the pulse of 80 and the respiratory rate of 18 seem inconsistent with the statement that "the patient appeared ill and pale." At any rate, there was no shock.

From the past history, one can say with reasonable certainty that the patient had gallstones. On the other hand, a predominating factor in all the attacks was nausea and vomiting. In uncomplicated cholelithiasis, that is not common. When nausea and vomiting occur, one should suspect some complication of stones, such as cholecystitis or pancreatitis. The late Dr. Daniel F. Jones used to say that patients with gallstones rarely vomit. In spite of this, I shall assume from the past history that the patient did have gallstones.

I should like to exclude ulcer in this case in spite of the fact that an x-ray diagnosis of ulcer was made thirteen years before entry. There is very little to suggest ulcer to me unless we were dealing with an acute perforation. It is reasonable to assume that there was no acute perforation because the patient was apparently not sick enough. There was tenderness, but no spasm. Widespread tenderness without spasm is certainly not consistent with peritonitis.

I assume that she had gallstones with some complication. One must bring out certain points about the history to decide what the complication might have been. It is impressive that the pain was steady and very severe, and yet the patient was not very ill, according to the record. Could she therefore have had acute cholecystitis? The majority of patients with acute cholecystitis in my experience are apt to have rather higher temperatures when we first see them and often have higher white-cell counts: 19,600 is a high count, but acute cholecystitis is often associated with a count of 30,000 or more. The patient may have had acute cholecystitis, but I doubt it.

What else might she have had? Acute pancreatitis must be considered, especially as a complication in cases of gallstones. Acute pancreatitis alone would not explain the repeated attacks for a period of three months, but she might have had stones and then a final attack of pancreatitis. At any rate, the steady pain, the excessive nausea and vomiting, the pain in the shoulder on deep inspiration, the elevated white-cell count and the chill, which occurred not at the onset of symptoms but some time afterward, suggest it.

In this particular case, it is a difficult matter to differentiate cholecystitis and acute pancreatitis

complicating gallstones. If we take the physical examination as it reads, I presume that we must exclude pancreatitis because no mention is made of tenderness in the left upper quadrant; it is all in the right upper quadrant. The pain in the shoulder was also on the right side. However, I should not be at all surprised if she did have acute pancreatitis for the reasons that I have mentioned. It is because of nothing more than the clinical picture that I should lay more emphasis on pancreatitis than on acute cholecystitis. An observation that would have been of great value in differentiating such a case seen early after the onset would have been a serum or urinary amylase determination, or both. In early cases of acute pancreatitis, it has been helpful in some patients. I am reasonably certain that the surgeon who operated on this patient did not believe it was pancreatitis. We have learned, of late years, the disadvantages of early operation in cases of this sort, but I should not be at all surprised if that is what she had in addition to gallstones. I do not believe she had cholecystitis.

#### CLINICAL DIAGNOSIS

Peritonitis, probably due to perforated gall bladder.

#### DR. SWEET'S DIAGNOSES

Cholelithiasis.

Acute pancreatitis.

#### ANATOMICAL DIAGNOSES

Foreign-body perforation of ileum.

General peritonitis.

#### PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: I am afraid that the description of the abdominal findings as given in the abstract must be very inadequate, since the preoperative diagnosis was rupture of the gall bladder and general peritonitis. I shall ask Dr. Allen to take up the story.

DR. ARTHUR W. ALLEN: The patient had had repeated attacks of acute abdominal pain for several months, and her physician was so convinced that these were attacks of gallstone colic that he had had two Graham tests performed outside. The clinical story was not too convincing, but we believed that the acute episode was probably associated with the gall bladder. We thought of acute perforation because there was too much generalized spasm and tenderness in the abdomen to be accounted for on the basis of simple acute cholecystitis, and we operated under the diagnosis of perforated gall bladder with peritonitis. At operation, it was obvious that the gall bladder and

everything in the upper gastrointestinal tract were normal — no perforation of an ulcer or of the gall bladder, which looked normal and contained no stones. We encountered, however, some thin pus and thought we must find out where it came from. We could not ignore the fact that it was there, and we therefore proceeded in a systematic fashion to look over the intestine; about midway in the ileum, we encountered a tiny perforation, a foreign body — a chicken bone — lying quite close to it. It was easy to poke it through the hole it had made in the intestine. But, of course, one could never make that diagnosis beforehand without roentgenograms, and we had not bothered to have them made. We did examine the foreign body by x-ray afterward, however, and if we had had a film before operation we probably should have had a better lead. My next bet was Meckel's diverticulum, without any thought of foreign body.

The patient had no recollection of having swallowed the chicken bone, but this must have occurred several months before; without any question, the bone was responsible for some of her previous attacks, since it pricked here and there on the way down.

DR. MALLORY: Here is the postoperative x-ray film of the chicken bone. The patient made an extraordinarily quick and uneventful recovery, the chart becoming flat within two days, despite the obvious generalized peritonitis found at operation.

#### CASE 28222

#### PRESENTATION OF CASE

A seventy-five-year-old woman was admitted to the hospital because of abdominal pain of several hours' duration.

She was in good health until early on the morning of entry, when she was awakened by moderately severe pain in the abdomen to the left of the umbilicus. She arose, and bathed, but the pain grew gradually much worse and extended all over the abdomen, going through to the back and around the ribs. There was no true chest pain, but there was costal-margin pain with deep inspiration. Following onset of the pain, the patient took only a few sips of water, which she vomited. There was but slight nausea, and no subsequent vomiting. A normal bowel movement occurred in the morning. A physician found abdominal tenderness, with pain coming in waves. He sent the patient to the hospital.

In the fifty years before entry, the patient had rare episodes of pain resembling the last attack. Three years before entry, she consulted a physician because of this. At this time, roentgenologic examination of the upper and lower gastrointes-

tinal tract yielded no diagnosis. Subsequent to this examination, one or two attacks of similar character occurred, going away after a few days. Occasionally, the patient experienced transient sharp pain in the lower lateral part of the left chest when frightened. She had had no dyspnea or ankle edema. Twenty years before entry, a diagnostic curettage was performed for bleeding.

Examination showed an elderly woman who complained of pain moving across her abdomen in horizontal waves from a point to the left of the umbilicus. The abdomen was quite rigid, with generalized tenderness, and was rather dull to percussion, although it was obviously distended. High-pitched peristaltic sounds were audible over apparently undilated portions of bowel at the time of passage of a wave of pain. The lung fields were clear. The heart was not enlarged, and there was a soft apical systolic murmur. The pupils were of pinpoint size.

The blood pressure was 170 systolic, 90 diastolic. The temperature was 97.5°F., the pulse 85, and the respirations 15.

Examination of the blood showed a white-cell count of 7400 with 93 per cent polymorphonuclears, and a red-cell count of 6,250,000 with 90 per cent hemoglobin. The urine was normal. The serum amylase was reported as elevated.

A roentgenogram of the abdomen showed elevation of the diaphragm and poor aeration of both lower-lung fields. There was no evidence of free air beneath the diaphragm. A dilated loop of bowel consistent with either ileum or sigmoid lay in the left lower quadrant. No other definitely dilated loops of bowel were apparent.

The patient was given venoclyses of glucose in physiologic saline solution and morphine sedation. In the next eighteen hours, the temperature and pulse rose steadily to terminal levels of 103°F. and 130 respectively. The abdominal distention increased, and the patient failed rapidly. Death occurred about twenty-six hours after onset of the illness.

#### DIFFERENTIAL DIAGNOSIS

DR. CHAMP LYONS: The salient features of this case are the age of the patient and the catastrophic events that started in the left upper abdomen. Pain of sudden onset became progressively severe and radiated through to the back. Nausea and vomiting were present initially but soon disappeared. The pain was wavelike, and the abdomen was distended and spastic. The presence of mild shock is indicated by the subnormal temperature and probably by the elevated red-cell count. The life-endangering character of the difficulty is emphasized by the early death of the patient.

Gallstone colic and acute appendicitis with perforation are unlikely because of the onset of pain in the left abdomen. Rupture in an ectopic pregnancy is excluded by the age of the patient. Dissecting aortic aneurysm is an unlikely possibility with persistent urine formation. Three diagnoses must be seriously considered: perforation of a benign or malignant gastric lesion, high intestinal strangulation obstruction and acute pancreatic necrosis. The colicky pain, the absence of air under the diaphragm, the absence of gas in the jejunum, the character of the peristaltic sounds and the elevated serum amylase suggest that acute pancreatic necrosis is the proper diagnosis. The low leukocyte count and the history of previous rare attacks of similar pain are characteristic.

Acute pancreatic necrosis is hemorrhagic at its inception. If death follows after three or four days, the pathologist usually finds a gangrenous pancreas, and if the patient succumbs at a much later date, the pancreas may be suppurative. *Clostridium welchii* is frequently present on culture. I believe that this pancreas was hemorrhagic, with evidence of retroperitoneal dissection of serosanguineous exudate containing *Cl. welchii*.

The etiology of pancreatic necrosis is variable. The main factors are direct trauma, vascular injury, infection and bile invasion. Biliary-tract disease is concomitant in about 60 per cent of the patients, but there was no history of biliary colic in this patient, and a previous x-ray examination of the upper intestinal tract was reported negative. The onset of the pain was in the early morning and not after a full meal. Hence, bile reflux seems an unlikely cause of this pancreatic disorder, although the history of rare attacks of pain for fifty years is consistent with a biliary etiology. There is nothing to suggest a traumatic or infectious etiology. The patient's age indicates the existence of arteriosclerosis, and I believe that a vascular accident is the most likely cause of the acute pancreatic necrosis.

DR. ALLEN G. BRAILEY: I should like to ask Dr. Lyons how he fits the presence of a dilated loop of bowel and cramplike peristalsis into this picture.

DR. LYONS: We are not sure that the gas was not in the sigmoid, and this acute episode starting in the left upper abdomen ought to have produced high jejunal strangulation, not lower ileal obstruction.

DR. TRACY B. MALLORY: Why should the pain of pancreatitis be crampy, however?

DR. LYONS: I do not know, but it is. There are two theories about it: one is that the celiac axis is involved in the inflammatory process, and the other is related to the persistent swelling of the capsule. I discount the capsule theory but am willing to accept the celiac-axis suggestion.

DR. RICHARD H. SWEET: It is very common to confuse the diagnosis of acute pancreatitis and acute small-bowel obstruction, and it is difficult to differentiate them. One point that I have always considered helpful is that the patients with pancreatitis have a steady, intense pain in the back.

DR. BENJAMIN CASTLEMAN: How about the white-cell count?

DR. LYONS: It is characteristically low in acute pancreatitis.

#### CLINICAL DIAGNOSIS

Acute pancreatitis?

#### DR. LYONS'S DIAGNOSES

Acute pancreatic necrosis, hemorrhagic, probably secondary to thrombosis or embolism of pancreas.

Peritonitis, acute (*Cl. welchii*).

#### ANATOMICAL DIAGNOSES

Acute hemorrhagic pancreatitis.

Cholecystitis, chronic.

Cholelithiasis, probable.

Peritonitis, acute (*Cl. welchii*).

Thrombosis of splenic vein.

Pneumoperitoneum.

Pneumohydrothorax, bilateral.

Arteriosclerosis, aortic and coronary, marked.

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: Post-mortem examination did show acute hemorrhagic pancreatitis in the distal half of the pancreas. The process had involved the splenic vein, which showed complete but fresh thrombosis, and there was not as yet necrosis of the spleen. Dr. Lyons prophesied that we might well obtain a positive culture for *Cl. welchii*. There was more obvious evidence of *Cl. welchii* infection, since gas gushed from the peritoneal cavity on our primary incision, and the liver and the spleen and some of the other tissues were grossly crepitant.

So far as the etiology is concerned, we have nothing positive to contribute. The patient did,

as most of these patients do, have severe biliary-tract disease. The gall bladder was small, firm and very fibrous, almost imbedded within the liver; it contained neither bile nor stones. The remaining biliary tract showed marked dilatation, with thickened walls and evidence of very longstanding chronic infection. Again, no stones were present in the ducts, but a small pigment stone that was found lying free in the duodenum may well have been squeezed out of the duct in our preliminary manipulations. Unquestionably, the patient had had severe infection of the biliary tract for several years. We did not make out any involvement of the celiac axis; she had moderate arteriosclerosis, which was not directly connected with this lesion.

DR. FLETCHER H. COLBY: Could the lesion have been due to bile reflux?

DR. LYONS: It is not likely that bile reflux caused the distal end of the pancreas to become necrotic.

DR. COLBY: How do you account for the *Cl. welchii*?

DR. LYONS: Dr. Lester Dragstedt\* has written an article on the pancreas in which he emphasizes the fact that *Cl. welchii* is important in this whole problem. His evidence is very good from an experimental point of view, and I think perhaps we have not paid enough clinical attention to it. I do not believe that the Welch exotoxin, which is extremely hemolytic, could have been active in this woman, since she had a red-cell count of over 6,000,000. I do not believe it was toxemia, or that treatment with *Cl. welchii* antitoxin would have been worth while. I am inclined to believe that this toxemia was the result of some action of the Welch bacillus on the pancreatic cells or a result of some bacterial poison that is a chemical constituent of the Welch bacillus itself. We do not know what it is, but it is almost universally associated with pancreatitis.

DR. COLBY: Where does the Welch bacillus come from?

DR. LYONS: It is always in the intestinal tract.

\*Dragstedt, L. R., Haymond, H. E., and Ellis, J. C. Pathogenesis of acute pancreatitis (acute pancreatic necrosis). *Arch. Surg.* 28:232-291, 1934

the next meeting of the General Court was unfortunate, particularly in view of favorable action on similar bills by the legislatures of certain other states, the sale of such drugs, however, is partially under federal control

According to Section 502 (f) of the Federal Food, Drug and Cosmetic Act,<sup>2</sup> a drug is considered to be misbranded "unless its labeling bears adequate directions for use." However, since Section 502 (f) states that a drug shall be deemed to be misbranded "if it is dangerous to health when used in the dosage, or with the frequency or duration prescribed, recommended or suggested in the labeling thereof," and since the Food and Drug Administration<sup>3</sup> has stated as its opinion that the barbiturates are included among drug products that are too dangerous for indiscriminate use, even if sold with labeling attempting to give adequate directions for use," most manufacturers are taking advantage of the exemption granted in the regulation of Section 502 (f) — namely, that the drug may be distributed if its label bears the statement, "Caution To be used only by or on the prescription of a physician."

Hence, the inspectors of the Food and Drug Administration are empowered to report any interstate shipment of a barbiturate — interstate shipment is believed to exist until the product is in the hands of the consumer — that does not bear on its label the above statement, in addition to the statement, "Warning May be habit forming, required by Section 502 (d)." Obviously, a retail druggist who dispenses a barbiturate in a container that is not properly labeled may be prosecuted, furthermore, the broader interpretation of the regulations prohibits the sale, other than on prescription, of such drugs, even in containers that are not misbranded. For the past year, the federal inspectors have conducted cross section investigations to determine the extent to which these requirements are being observed by the retail druggists, and although only one legal action has been brought on the basis of improper retail sales, further proceedings will be inaugurated if such sales continue. Of course, the Food and Drug Admin

SUBSCRIPTION TERMS: \$6.00 per year in advance postage paid for the U.S. and possessions; \$3.50 per year; Canada \$7.04 per year; foreign funds \$8.52 per year for all foreign countries belonging to the Postal Union.

MATERIAL for early publication should be received not later than noon on Friday.

## REGULATION OF SALE OF BARBITURATES

A RECENT study<sup>1</sup> by a committee of the Connecticut State Medical Society gives ample proof of the conviction that the promiscuous use of barbiturates should be a matter of public concern and that these drugs should be sold only on prescription. That the same sentiment is held by the physicians in Massachusetts is evidenced by the fact that a recent legislative bill to limit the retail sale of barbituric acid, its derivatives and certain other sedatives to those possessing prescriptions from duly registered physicians, dentists and veterinarians was supported by the Massachusetts Medical Society. For this bill to be postponed to

istration has no control over products manufactured and sold within Massachusetts.

At least some advance has been made toward prohibiting the over-the-counter sale of barbiturates, and the legislatures of all states should create statutes, conforming with the regulations of the Food, Drug and Cosmetic Act, that will completely eradicate the evil.

### PULSE—AND THE FUTURE

WITH an ever-increasing percentage of recent medical graduates called to the colors, a correspondingly greater burden falls on those too old for active military service and on those still in that period of training without which they would be of little use—as physicians—either in civilian or in military life. The former group has had experience, dulled a little, perhaps, by advancing years, but it is on the younger men that much of the burden of the present war must necessarily fall, although too many of them seem unaware of this trenchant fact. Plans for and visions of the future should not and must not come entirely from the older group. No matter what the fortunes of the next few years, a new era is being opened up, of which the mainstay will patently be the youth of today: the medical student of 1942 is the army officer of tomorrow. It is but just and proper, therefore, that their views—whether right or wrong—be publicized in some material manner. Since this country is fighting for democracy, a democracy to fight for must exist.

*Pulse*, which is the official publication of the New England section of the Association of Internes and Medical Students, expresses the views of one portion of the medical youth of America, and there is reason to believe that there are nonmembers who hold similar views. Some, of course, do not

agree; and hereon rests the responsibility of the editors of the publication: they must be rigorous in their efforts to represent truly the constituency under whose name they have chosen to promote themselves.

What are the purposes of this organization? It aims to serve the best interests of medical students and interns, wherever they may be, and to maintain and advance the ideals of the medical profession, thus serving society in general without respect to race, creed or color. More specifically, now that the United States is at war, this association aims to rally every medical student to an all-out war effort, to aid civilian defense by the training of Red Cross crews and catastrophe squads, to furnish, so far as possible, medical aid to the United Nations and to investigate what immediate changes might profitably be made in the curriculums of medical schools, so that these courses of study may be drawn more closely into line with the needs emerging from the present crisis. The members further wish to help in assuring that internships are of maximal educational value now that but one year is guaranteed and further training—except for service in the Army or Navy—is difficult to obtain.

In the April issue of *Pulse* appears an illuminating analysis of the financial needs of medical students under the new twelve-month medical-school system. One has, in a vague way, been aware that financial hardships must inevitably fall on some students under the new system, and although the constituted authorities are making every effort to avoid undue hardships, the average physician—who might be of help in one way or another—has not been apprised of the true state of affairs. The article is well worth study by all who are interested in the future of medicine.

*Pulse* is distributed as widely as circumstances permit among medical students, interns and physicians, and its columns are open to contributions as are those of any other periodical. Those who desire to obtain copies or to submit short articles should address their letters to 368 Longwood Avenue, Boston.

## MEDICAL EPONYM

## PARRY'S DISEASE

Sir William Osler considered that if any name should be attached to the syndrome of exophthalmic goiter, it should be that of Caleb Hillier Parry (1755-1822), M.D., F.R.S., whose description was published posthumously by his son in *Collections from the Unpublished Medical Writings of the Late Caleb Hillier Parry* (London, 1825; Vol. 2, p. 111). The condition is described under the general heading, "Diseases of the Heart":

*Enlargement of the Thyroid Gland in Connection with Enlargement or Palpitation of the Heart.* There is one malady which I have in five years seen coincident with what appeared to be enlargement of the heart, and which, so far as I know, has not been noticed, in that connection, by medical writers. The malady to which I allude is enlargement of the thyroid-gland.

This introduction is followed by the report of 8 cases showing a thyroid tumor with symptoms of tachycardia, exophthalmos and edema (1 case), of 7 cases of swelling of the thyroid gland with tachycardia or palpitation and of 5 cases of thyroid enlargement without heart symptoms.

CASE HISTORY: FATAL PERNICIOUS  
VOMITING IN PREGNANCY

A thirty-one-year-old primipara was sent to the hospital toward the end of the third month of pregnancy because of nausea and vomiting. The past history was irrelevant. Although the patient had been married sixteen years, this was her first pregnancy. Physical examination showed no abnormalities other than moderate dehydration and a pulse elevated to 100. The nausea began about the sixth week, and treatment at home had been instituted; since the patient did not improve, she was hospitalized. Administration of insulin, glucose, adrenocortical extract and transfusions resulted in marked improvement for a few days, and she was sent home. Ten days later, she returned to the hospital in extremis and died without surgical intervention.

Autopsy showed acute parenchymatous nephritis, acute degenerative hepatitis, congestion of the spleen and early degeneration of the adrenal glands.

*Comment.* Pernicious vomiting, and this was a true case of pernicious vomiting, should not result

in death. The patient should have been hospitalized earlier. The treatment at the hospital did result in improvement, but it was probably not sufficient to warrant discharge.

The modern treatment of pernicious vomiting in pregnancy consists of hospitalization, the cessation of all food by mouth for forty-eight hours, the use of intramuscular thiamine chloride and intravenous glucose, and sedation. If this treatment is begun before definite degenerative disease has developed, improvement is rapid and remarkable. Rarely do such cases reach the point where therapeutic abortion is indicated to save life. This patient did not have thiamine chloride, but she did have glucose and transfusions. It is very probable that religious beliefs prevented surgery.

There is no such thing as pernicious vomiting per se in pregnancy. Death in these cases is due to pure starvation, which results in acidosis and degenerative changes in the kidney and liver.

One cannot help believing that this death was entirely avoidable. Earlier hospitalization and the routine treatment would probably have resulted in recovery. Therapeutic abortion was apparently not considered. Patients not treated early enough may need therapeutic abortion to prevent death, but this procedure, when a case has been intelligently handled and hospitalized early, is practically never necessary.

## DEATHS

DELAHANTY — WILLIAM J. DELAHANTY, M.D., of Worcester, died May 10. He was in his eighty-fifth year.

A native of Fitchburg, Dr. Delahanty received his degree from Dartmouth Medical School in 1883. He was an incorporator and a member of the staff of St. Vincent's Hospital, and was on the staff of the Worcester City Hospital for more than fifty years. He was a trustee of the Worcester State Hospital, and was a fellow of the Massachusetts Medical Society and the American Medical Association.

FIELD — HENRY M. FIELD, M.D., of Norwood, died May 20. He was in his sixty-eighth year.

Dr. Field received his degree from Harvard Medical School in 1904. He was a member of the staff of the Norwood Hospital, and a fellow of the Massachusetts Medical Society and the American Medical Association.

His widow survives him.

O'LEARY — CORNELIUS J. O'LEARY, M.D., of Brighton, died May 20. He was in his fortieth year.

Born in Charlestown, Dr. O'Leary received his degree from Tufts College Medical School in 1933. He had been associate medical examiner for the northern district of Suffolk County for seven years and was a fellow of the American College of Surgeons, the Massachusetts Medical Society and the American Medical Association.

His widow and four children survive him.

## WAR ACTIVITIES

### CIVILIAN DEFENSE

#### NEW PUBLICATIONS

*Protection of Hospitals*, Bulletin No. 3 of the Medical Division of the United States Office of Civilian Defense, prepared in collaboration with a special committee of the American Hospital Association, has now come from the press in its official form. It was previously published in several hospital journals in order that the material could be used by hospitals at the earliest possible moment.

The bulletin discusses protection of hospitals against air raids under the following heads: protection of building fabric, patients and personnel; protection of glass; ventilation; protection against fire; rescue squads; air-raid shelters; blackout regulations; protection of utilities; facilities for care of casualties; unit system and reserve stocks; the ambulance entrance; morals; distribution of casualties to wards.

Diagrams show how sandbag barricades can be used for temporary reinforcement, how to protect windows against shattering of the glass without cutting off ventilation, and several methods of blacking out. There is a sketch suggesting how an ambulance entrance can be designed to eliminate unnecessary turns, and there are also designs for signs to guide ambulances in the blackout.

The section on protection of glass gives detailed instructions on materials that can be used and methods of applying them. Under "Protection against Fires," there is a description of the various types of incendiary bombs and of the approved methods of fighting them. The report emphasizes the importance of fire and evacuation drills.

Facilities especially needed for the care of war casualties are a special reception room, in which casualties may be examined to determine their condition and immediate treatment, operating rooms in protected parts of the hospital (lower floors or basement), decontamination station for gas casualties and ample provision for a mortuary.

*Volunteers in Health, Medical Care and Nursing* has been issued for use of executives in civilian defense volunteer offices and of executives of agencies using volunteer services in these fields. The pamphlet outlines qualifications and duties for the following activities: automobile drivers, blood donors, child-care assistants, first-aid teachers, home-nursing teachers, health-department assistants, hospital and clinic assistants, laboratory assistants, library assistants, medical social-service assistants, nurses' aides, nutritionist assistants, occupational-therapy assistants, physiotherapy assistants and sanitation assistants.

## MISCELLANY

### DANGERS OF INDIRECT CONTACT WITH TUBERCULOUS PATIENTS

As long ago as 1865, Villemin successfully passed the "virus" of tuberculosis from one animal to another. Twelve years later (five years before Koch's discovery of the tubercle bacillus), von Tappeiner caused dogs to develop tuberculosis by allowing them to inhale sputum from a consumptive patient. Although direct lip contact is today considered the most potent means of transferring tubercle bacilli from person to person, knowledge of the relative dangers of indirect contact with tuberculous lungs and their secretions is still incomplete. Three recently published papers give evidence of this and, at the same time, sharpen one's perception of the manner in which bacilli go from host to victim.

### THE OCCURRENCE OF TUBERCLE BACILLI ON BOOKS AND GAIMENTS HANDLED BY PATIENTS WITH OPEN TUBERCULOSIS

(Jacobs, M. A., and Petroff, S. A. *Quarterly Bull. Sea View Hosp.* 7:33-39, 1941.)

Books read by tuberculous patients probably are occasionally contaminated by sputum in the form of droplets expelled during coughing or speaking as the book is closely held to the face or at such a level that any droplets expelled may readily be deposited upon the paper. Also they may contaminate books by licking the thumb or finger when turning the pages. Transmission of infection to a second reader appears likeliest to occur when the recipient with moist thumb or finger handles the contaminated pages, supposedly harboring the bacilli.

There is a general agreement that large portions of the bacilli deposited on the pages become dry and nonviable after a short time. Kenwood and Dowe exposed papers to coughing patients and dried them for one month, after which the washings from the paper surfaces were inoculated into guinea pigs of which not a single animal developed tuberculosis. Other experiments of this kind point to the conclusion that although the risk of infection from books is not to be belittled, the possibility of transmission from such channels is extremely small.

Jacobs and Petroff permitted certain patients with advanced pulmonary tuberculosis, with uncontrollable cough and with sputum of Gaffky 6 to 8, to handle books carelessly as possible. They coughed on the marked pages, and wet their thumbs with saliva when turning the pages. Scrapings later derived from the marked pages were collected and suspended in physiologic saline solution. Tuberculin-negative guinea pigs were inoculated with this solution. Three of the 16 guinea pigs died from intercurrent disease, and no evidence of tuberculosis could be found at post-mortem examination. The other remained tuberculin negative ninety-two days after inoculation, when they were sacrificed.

Another set of experiments demonstrated that the droplets collected by scrapings from garments worn by patients with open tuberculosis did not infect guinea pigs. However, this failure should not give rise to a sense of false security and to a laxity of precautionary measures. The summary includes the following suggestions:

At present, the best way to ease the mind of the possibility of transmission by a book that has been handled by a patient with open tuberculosis is to store or quarantine the book for several weeks until the morbid material is completely dried, since it has been shown repeatedly that the drying robs the bacilli of their power of producing disease in animals. This measure was recommended by the British Joint Tuberculosis Commission.

There is no suggestion of importance concerning the patients' garments should be disinfected. Perhaps the safest way is to expose them to the sun and air for a few days before storing them away.

### SURVIVAL OF TUBERCLE BACILLI

(Smith, C. R. *Am. Rev. Tuberc.* 45:334-345, 1942.)

Cultures were made from swabbings of bedside tables, lamps, bed frames and other articles in rooms occupied by patients at Barlow Sanatorium, and from room dust sweepings and cotton filters through which room air had been sucked. Uniformly negative results led to speculation regarding the effect of daytime roomlight on living tubercle bacilli.

Review of the literature seems to sustain the statement

Park and Williams that "Tubercle bacilli in sputum when exposed to direct sunlight are killed in from a few minutes to several hours according to the thickness of the sputum and the season of the year. They are usually destroyed by diffuse daylight in from five to ten days. Dried sputum in rooms protected from abundant light has occasionally been found to contain virulent tubercle bacilli for as long as ten months."

For the present experiment, suspensions of virulent human tubercle bacilli in water or in sputum were spread on cover slips in 0.05-cc amounts and allowed to dry. Some of these preparations were placed in a small unheated room in the light of an unglazed but screened north window through which the sun was known never to shine, others were kept in complete darkness within a cardboard box inside a second such box, which in turn was kept in a table drawer of an unheated room. This was done during a clear, dry period in midwinter at Los Angeles.

A second set of tests was run in the early spring during cloudy and rainy weather, and a third set of tests in midsummer. The following winter, viability was also tested in the electric refrigerator.

The viability of tubercle bacilli was determined by animal inoculation and by culture.

Dried tubercle bacilli survived unfiltered north room light from four hours to five days under varying conditions. They were nonviable, according to the methods of recovery used, at one to twelve days, the viability was not established in one case.

Viability in the dark was from less than forty days to between three and a half and five months.

Viability in the refrigerator was between six and a half and fourteen months.

Tubercle bacilli were more readily recoverable and after longer periods of exposure when the dose deposited was larger. They lived longer in smears made from sputum than in those from water suspensions. They lived longer in the winter than in the spring and summer.

Variations in relative humidity and periods of partial cloudiness had no effect on viability.

Unfiltered daytime roomlight probably plays a very important role in preventing cross-infection and in protecting the employees of tuberculosis sanatoriums.

#### THE DISSEMINATION OF TUBERCLE BACILLI FROM FRESH AUTOPSY MATERIAL

(Sloan, R. A. *New York State J. Med.* 42 133, 1942)

Two incidents seem to have prompted this study: the isolation of acid fast organisms from the surface of eye glasses worn during an autopsy on an active case of tuberculosis, and the observation that the incidence of tuberculosis among medical students appears to be proportional to their contact with autopsy material during the second year in medical school. The compression of the crepitant lung, causing expulsion of minute amounts of bacterial laden air, might simulate a human cough and thus be responsible for the dissemination of bacteria.

Lungs from patients who died from tuberculosis were sectioned in the usual manner, the trachea was opened, regional lymph nodes were examined, and all cavities were opened with scissors. This was done under a shield, equipped with a glass plate situated about 20 cm. directly above the specimen. After a fifteen minute examining period, the plate was washed with sterile saline solution.

The growths obtained from the washings led to the conclusion that methods of examination that make use of a compression technique in atmosphere in

the vicinity of the autopsy, and that fresh tuberculous lungs are decidedly dangerous and are a potent source of atmospheric contamination, against which methods of proper protection should be devised.—Reprinted from *Tuberculosis Abstracts*, May, 1942

#### NOTES

Seven appointments to the teaching and research staffs of the Harvard Medical and Dental schools were recently announced by Harvard University as follows: John B. Hazard, MD Harvard '30, of Wellesley, assistant in pathology; Mark S. Donovan, MD University of Michigan '35, of Boston, assistant in roentgenology; Luke Gillespie, MD Harvard '37, of Windrop, assistant in obstetrics; Dario Azevedo, MD Faculty of Medicine, of Lima, Peru, '30, research fellow in physiology; Zenal Kiper, MPH Harvard '40, of Boston, research fellow in surgery; Francis Rouilland, MD Harvard '27, of Cambridge, assistant in obstetrics; and Richard D. Garrett, DMD Harvard '39, of Glens Falls New York, assistant in surgery.

Harvard University has recently announced the appointment of J. Howard Mueller, PhD, as professor of bacteriology and immunology at Harvard Medical School and School of Hygiene and Public Health, a position made vacant by the death of Dr. Hans Zinsser in September, 1940. Drs. Fuller Albright, Allan M. Butler and Hiram H. Merritt were promoted to associate professorships in medicine, pediatrics and neurology, respectively, and Dr. Frederick J. Stare, a graduate of the University of Chicago School of Medicine, was named assistant professor of nutrition.

At a recent meeting of the American Association of the History of Medicine, the William Osler Medal was awarded to John T. Barrett, 43, of Boston University School of Medicine.

Dr. Leopold F. King, of Lowell, was recently elected president of the Massachusetts Society of Examining Physicians. He succeeds Dr. Roger T. Doyle.

Dr. Walter B. Cannon, George Higginson Professor of Physiology at Harvard Medical School, has recently been made an honorary member of the Russian Academy of Sciences. Two other Americans and two Englishmen were similarly honored, this being the first time since the Russian revolution that such distinction has been granted to foreigners.

#### REPORTS OF MEETINGS

##### CARNEY HOSPITAL JOURNAL CLUB

At a regular monthly meeting of the Carney Hospital Journal Club at the hospital on January 8, Dr. Robert Wilkins, of the Evans Memorial Hospital, spoke on "Recent Developments in the Pathological Physiology of Hypertension." After briefly reviewing the fundamental work of Goldblatt, on which most experimental investigation in this field is now based, Dr. Wilkins discussed the types and characteristics of experimentally produced hypertension. The first general type is popularly known as that caused by "renal ischemia." This was originally effected by Goldblatt by applying a clamp on the renal artery and was later produced by the artificial constrictive perinephritis of Page's cellophane capsules. That any changes in such cases are not truly the result of anoxia of the kidney is now generally accepted, since experiments have

demonstrated that there is no decrease in the blood flow to such an organ. The significant change is apparently one from a pulsating to a steady type of blood flow.

The following facts are characteristic of such hypertension. It is cured by removal of the involved kidney. The blood pressure may not immediately return to normal, apparently depending on the duration and degree of the hypertension. This is probably associated with its effect on the other kidney. Wilson and his co-workers have shown that the clamp keeps the elevated blood pressure from affecting that kidney, whereas the normal organ is adversely affected. Hypertension is increased if the normal kidney is removed; this indicates that the latter in some manner protects the animal. The onset of hypertension is not prevented, nor is its course altered by renal denervation, complete sympathectomy or pithing; this type of experimental hypertension has no relation to renal innervation and is probably humoral in its mechanism.

The second general type of experimental hypertension is the so-called "neurogenic" kind, which is produced by removal of the carotid sinuses and the depressor nerves (Heyman's operation) or by artificial increase of the intracranial pressure (Cushing). The characteristics of this type are its lability, its abolition by pithing or complete sympathectomy, and its failure to be eliminated if only the renal (adrenal) or the cardiac innervation is intact. This, then, is essentially a nervous mechanism as compared with the humoral character of the other type.

The relation of such hypertension to the human form is borne out by the fact that at least certain cases in man seem to have some degree of "renal ischemia." Furthermore, splanchnic sympathectomy has a definitely beneficial effect in certain cases. And since this operation removes both the renal and adrenal innervation, it is conceivable that the kidney is a common factor. In further support of this hypothesis are the observations that in hypertensive patients there is a vasoconstriction of the efferent renal arterioles, as demonstrated by Smith's Diodrast-clearance and inulin-clearance tests, and that the blood of such patients is more vasoconstrictive than that from normal controls (Page).

Another problem is the character of "renin," a substance that is obtained from kidneys and is the precursor of angiotonin and hypertensin, which are now being employed to produce experimental hypertension. Earlier preparations of this compound were apparently impure, for they caused a depressor effect after the pressor. It has now been demonstrated that this substance is a protein, is heat labile, and combines with a pseudoglobulin to produce angiotonin, the last reaction being dependent on the temperature, the time and the proportion of reacting substances. All these are, of course, characteristics of an enzyme. Angiotonin (hypertensin), on the other hand, is a protein that is heat stable, dialyzable and crystallizable, and is destroyed by an excess of renin or tissue extracts. Therefore, it is a relatively pure substance but is not an enzyme.

The crucial experiment attempted by Dr. Wilkins and his co-workers was to determine whether angiotonin causes human hypertension of the proper pattern. For this purpose, they used themselves as subjects and employed angiotonin supplied by Page. It was concluded that this substance does cause a characteristic and marked hypertension, without any significant side effects, in the majority of subjects. There is often dizziness at the onset, and some subjects later experienced substernal oppression and palpitation. One doctor complained of severe headache closely resembling that of hypertension.

This indicates that these symptoms, so often clinically attributed to a superimposed "neurosis," are in reality the result of the high blood pressure. There was a significant rise in the blood pressure (190 systolic, 120 diastolic). Bradycardia, a constant finding, could be abolished by atropine, whereas the hypertension was heightened. The venous pressure, surprisingly, rose to failure levels, with visible neck veins in certain cases. There was a concomitant decrease in vital capacity. The cardiac output, as suggested by Starr, was sharply diminished. This is the only pressor substance that acts in this way, according to this observer, who has reported that adrenalin, amphetamine (Benzedrine) and so forth either do not change the output appreciably or increase it. These findings suggested the similarity to cardiac failure, and this was borne out further by teleoroentgenograms and chest plates, which revealed increased lung markings or enlargement of the cardiac shadow, or both. That there is peripheral vasoconstriction was corroborated by skin temperatures and plethysmographs. That angiotonin is a true vasoconstrictor independent of the sympathetic nervous system was proved by its action in the absence of this system and when injected intra-arterially and at skin temperature to the part measured. It does not overcome sympathetic control, however. Whether the hypertension resulting from angiotonin is the same as the naturally occurring disease depends on how one wants to interpret the evidence, for there are some facts in favor of both views. The lack of any increase in venous pressure in the human disease, unless there is cardiac failure, is in contrast to the experimental facts, but the cardiac failure is an acute episode. The spasm of the renal efferent arterioles is found in both conditions. Page and Houssay both hold the opinion that the substance causing human hypertension is either similar to or the same as angiotonin (hypertensin).

Since the presence of a normal kidney acts as a protection against both types of hypertension, there have been numerous attempts to find depressor substances in normal kidneys to counteract the pressor material from abnormal renal tissue. Such depressors act only if there is a high blood pressure. In all the outstanding laboratories, there are now such materials, which decrease the hypertension in animals and in certain human subjects. Since there are many severe reactions at first, Page has so far employed his depressor only in very advanced cases and in practically moribund patients. Nevertheless, he is firmly convinced that he is gradually obtaining a purer substance and that the reduction of blood pressure is not attributable to the side reactions of shock, fever or toxic manifestations, as some observers maintain. In favor of his contention is the slow and prolonged reduction of blood pressure, in contrast to the precipitous fall in toxic reactions and shock. Furthermore, there have been satisfactory results in some patients without side reactions, whereas some of those with the severest toxic manifestations revealed no fall in pressure. The hypertension returns if this therapy is not continued. All the measurable signs, such as increased cardiac output, decreased venous pressure and efferent arteriolar dilatation, testify to the efficacy of this "antiangiotonin."

Schroeder, in New York, working from the chemical standpoint that all these compounds have the basic structure of tyrosinase, has used this substance to render angiotonin inactive *in vitro*. It definitely decreases the hypertension in experimental rats, but its use in human beings is not advocated. It was advanced as a method of investigation, and is too difficult technically to be used in man.

Another form of therapy of human hypertension that has met with success in some cases in the hands of certain

surgeons such as Peet and Smithwick, is sympathectomy. The question arises whether it is merely palliative and non-specific but there is no doubt of its efficacy in properly selected cases. It should be noted that there is no measurable increase of renal blood flow after this operation. In considering human hypertension in general, one should realize that it is not a simple problem, for apparently civilization adds some conditioning factor, as evidenced by the lack of this syndrome in the Australian aborigines and in Negroes in their native African countries. Whether this indicates the presence of a neurogenic factor is still a moot point.

In answer to questions, Dr Wilkins pointed out that such therapy as might result from the introduction of a gonitoin inhibitors will probably have to be periodic and continuous like insulin. In certain cases in which a cycle is present, it might be possible to break in and thus allow smaller doses or less frequent administration of the material. The strong heredity factor and neurogenic pattern in human hypertension are corroborated by previous tests of any type (immersion of hands in cold water) which demonstrate that hypertensive patients show a stronger reaction and that there is a higher percentage of future hypertensive patients in present hyper reactors and their children than in those showing a normal response.

#### NEW ENGLAND PATHOLOGICAL SOCIETY

A regular meeting of the New England Pathological Society was held on January 15 at the Evans Memorial Massachusetts Memorial Hospitals. Dr B Earle Clark presided.

The first paper, Experimental Allergic Inflammation of the Intestine was presented by Dr George Hartley. Previous work suggested that ingested antigen is localized in the intestinal wall by specific antibodies. Because the work of Opie and others has shown that allergic inflammation in the skin (the Arthus phenomenon) is caused by a localization of antigen by antibodies, the demonstration of such a reaction in the intestine would prove that antigen is localized by antibodies in this organ. Following the injection of crystalline egg albumen into the rectum or directly into the wall of the cecum of hypersensitive rabbits, a severe inflammatory reaction developed locally. A similar inflammatory response was produced in the ileum of hypersensitive rabbits following the injection of antigen into a small radicle of the mesenteric artery. The inflammation was characterized by a marked neutrophilic infiltration of the entire wall (mucosa, submucosa, muscularis and serosa), edema and slight hemorrhage of the submucosa, and vascular congestion of the submucosa and subserosa. Eosinophils in rabbits are difficult to distinguish from neutrophils but Dr Hartley believes that there was an infiltration of these cells as well as of the neutrophils, in the intestinal wall. At the site of the mesenteric arterial injections, acute arteritis and periarteritis developed. No lesions were present in the normal control rabbits that were treated in the same manner as the hypersensitive animals. All the lesions were present after twenty-four hours. Older lesions have not yet been studied. These experiments demonstrate for the first time the direct production of allergic ileitis. The resemblance of this allergic inflammation of the intestine in rabbits to acute appendicitis and the nonspecific inflammations of the small intestine in human beings suggest the possibility that some of these inflammatory reactions may be allergic. Finally, since it has been definitely established that allergic inflammation in the skin (the Arthus phenomenon)

is the result of the localization of antigen by antibodies, these experiments suggest that antigen is localized by specific antibodies in the intestinal wall.

In the discussion, it was questioned whether Dr Hartley had justified his conclusions. The fact that the histologic preparations of his experimental animals resembled appendicitis and ileitis was insufficient to prove that these diseases are allergic. Dr Alvin Moritz warned against giving too much emphasis to the eosinophil as evidence of an allergic state.

The next paper, Temporal Arteritis. Report of a case, was presented by Dr David Skinner. Biopsy of one temporal artery showed moderate thickening of all the coats, with preservation of the internal elastic membrane. The adventitia and portions of the media were replaced by old granulation tissue. The adventitia, media and intima were heavily infiltrated with endothelial lymphocytes, occasional plasma cells and very rare eosinophils, but no giant cells were observed.

In the discussion Dr Tracy B Mallory reported that he had seen 6 cases at the Massachusetts General Hospital. He brought out the point that the vessel changes can usually be distinguished from periarteritis nodosa microscopically but that occasional difficulty may be encountered in differentiating it from thromboangitis obliterans.

Another paper Spontaneous Renal Infarction in Infants was presented by Dr Skinner. During the last fourteen years 8 cases of renal infarction have been observed among 462 consecutive autopsies on infants one year old or younger exclusive of stillbirths. The infarct was bilateral in 7 cases total in 4, and partial in 2. Venous thrombi were present in 3 cases. Associated conditions were pneumonia in 5 cases, cleft palate with malnutrition in 2, acute enteritis in 2 and marasmus in 2. No definite cause for the infarction could be determined. The next paper Wilson's Disease. Report of a case, was presented by Dr Donald Nickerson. A twenty-five year-old woman was admitted to the hospital complaining of enlargement of the abdomen and pain in the left upper quadrant. The patient had been perfectly well until the age of fifteen, when she began to have irregularity of the menstrual periods, followed by complete amenorrhea nine years later. On examination, the outstanding finding was a very large spleen, which reached to the crest of the ilium, and a painful subcutaneous nodule just above the umbilicus. Neurologic examination showed no definite spasticity but a coarse shaking tremor of both hands, hyperactive knee and ankle jerks, no interference with sensorium and evidence suggesting cerebellar dysfunction. Laboratory examination showed a rather marked secondary anemia, with moderate achromia and poikilocytosis. Blood chemical studies, including cholesterol, calcium, phosphorus, phosphatase and total protein were essentially negative. The sedimentation rate was moderately active. The spinal fluid examination, blood and spinal fluid serologic findings, blood fragility studies and repeated Bence-Jones determinations on the urine were all negative. A x-ray examination showed marked splenomegaly and moderate demineralization of the skeleton. The patient who was discharged from the hospital with a diagnosis of Wilson's disease, progressed fairly well for nine months, during which time she had been studied in a Boston hospital, where the same diagnosis was made. The last admission was due to marked abdominal enlargement with edema of the ankles, for which paracenteses were done, on the sixth hospital day a fatal hemorrhage into the intestinal tract occurred. Post mortem examination showed an extreme cirrhosis of the liver, which weighed 675 gm and whose gross and

microscopic appearance was that of a healed acute yellow atrophy. The spleen was markedly enlarged, weighing 740 gm., and showed no gross lesion beyond extreme engorgement. There was a small, perforated, esophageal varix from which a fatal hemorrhage had occurred. Examination of the brain showed distortion of the relation of the left basal ganglia, and microscopic sections showed rather extensive gliosis in the left lenticular area.

In the discussion, Dr. Ernst E. Mathias suggested that Wilson's disease may be one of a group of diseases, the other members being Huntington's chorea, pseudosclerosis and athetosis.

The final paper, "The Mitotic Activity of a Group of Colchicine-like Compounds," was presented by Dr. Charles Branch. It has been established that colchicine is a toxic drug that has a profound effect on cell division. Several investigators have attempted to find a substitute or derivative of comparable activity but less toxicity. The present study was concerned with a group of twelve such compounds, tested for their effect on mitotic activity. For each experiment, 50 mice (Strain C57), planted with sarcoma (Strain 37), were used. The compound to be tested was injected in varying doses, and the mice were sacrificed at regular intervals, up to twenty-four hours. Compounds differing considerably in their chemical structure all produced mitotic showers comparable to colchicine, but were apparently less toxic than that drug. Several of the animals with varying sized tumors were displayed.

## BOOK REVIEWS

*School Health Services: A study of the programs developed by the Health Department in six Tennessee counties.* By W. Frank Walker, Dr.P.H., and Carolina R. Randolph. 8°, cloth, 197 pp., with 139 tables and 12 charts. New York: The Commonwealth Fund, 1941. \$1.50.

In view of the steady growth of school health services in this country and the relatively important place they occupy in the public-health program, a critical study of objectives and the results obtained is long overdue. The authors have attempted such a study in a group of Tennessee counties where school health work has been well organized for ten years, and where uniformity of both examinations made and records kept far exceeds the average.

The main objective is the appraisal of certain standard procedures in terms of pupil response. The dominant influence of the presence of the parent at the time of examination comes as no surprise. Nursing supervision alone had much less influence in securing the correction of defects, but was far from negligible. Although preschool health supervision definitely increased the percentage of immunization of children against diphtheria and typhoid fever, it showed no effect on the percentage vaccinated against smallpox. A satisfactory response in all three kinds of immunization followed school supervision.

Some of the questions raised by this study are perhaps more significant than the conclusions that could be drawn. How far can routine school examinations go without interfering with more productive activities in the public-health program, or even with the correction of defects found? One might also ask how far a health department should go with school procedures that involve personal rather than public health. In terms of results, are routine dental examinations justified unless the community can provide corrective treatment when needed?

The authors' clear style and concise statement will appeal to the general reader, and the public-health worker will find in the book a challenge to more objective think-

ing in a somewhat nebulous field. The printing and format of the book uphold the usual high standard of the Commonwealth Fund publications.

*A History of Medical Psychology.* By Gregory Zilboorg, M.D., in collaboration with George W. Henry, M.D. 8°, cloth, 606 pp., with 21 illustrations. New York: W. W. Norton and Company, Incorporated. \$5.00.

Nobody in America writes with more fluency than Gregory Zilboorg. As a leader in medical thinking he has brought to this country the best of the European tradition. This new volume on the history of medical psychology is not merely an account of what has happened but also a critical appraisal, intelligently organized and interestingly told. Up to the present time, no book more scholarly than this has appeared in English. How Dr. Zilboorg has been able to do it in the midst of his heavy work as a psychiatrist and psychoanalyst is explained in part by the fact that he has had the assistance of Dr. George W. Henry.

Although Dr. Zilboorg is himself a psychoanalyst, it cannot be said that this book suffers from psychoanalytic bias. It is written from the philosophic and humanitarian point of view. Only a physician with broad human contacts and vast learning could have produced this document, on which every physician can afford to look with pride.

This book is not for light reading, although there are many parts of it that are charming and amusing. Rather, it is a book for study and reference. It is a book one could keep on one's bedroom reading table, where in quiet and in reflection one could appreciate the scope and profundity of Dr. Zilboorg's labors.

Dr. Zilboorg points out several important facts that until now have not been adequately stressed. His emphasis on the neuroses (Chapter 9) and on "psychiatric revolutions" (Chapters 7 and 11) will guarantee the reader ample reward for reading these sections if he has not time to read the whole book.

Dr. Henry's separate contribution on mental hospitals (Chapter 14) is well worth reading, since the facts it contains should be common knowledge to every physician in America today.

*About Ourselves: A survey of human nature from the zoological viewpoint.* By James G. Needham, M.S., Ph.D. 4°, cloth, 276 pp., with 45 illustrations. Lancaster, Pennsylvania: The Jaques Cattell Press, 1941. \$3.00.

The complex story of the development of animals and man is retold in a simple, often humorous, way by the former professor of entomology at Cornell University. There are chapters on the primates, man's remote ancestry, the development of the nervous system, instinct, learning, infancy and similar topics. The material is presented in language that a young adult could understand; this is an oft-repeated story, but well done, as might be expected from a well-trained biologist.

The last half of the book deals with a larger problem—society in its biologic aspects. Here one touches medicine, government, war, folkways, social behavior and human affairs. One senses that the author is not so happy in this broader field; certainly, his knowledge of medicine leaves much to be desired. For example, he gives eight symptoms of hysteria, no one of which would be accepted by a physician as diagnostically significant (page 216).

It is difficult for the reviewer to decide for whom this book was written. A grade school or college underclassman might profit by Part 1; Part 2, for adults, seems of less value.

## SOME REMARKS ON THERAPY FOR ANEMIA\*

WILLIAM B. CASTLE, M.D.†

BOSTON

I AM sincerely appreciative of the honor bestowed on me by the invitation to deliver this oration. As you are aware, my distinguished predecessors have annually instructed and entertained you with words both wise and charming. I wish, especially at this preprandial hour, that I were able to do so. Lacking such gifts, however, I have believed that in accepting this honor it would be a more suitable expression of appreciation were I to speak of matters of detail with which I have some experience than to discourse, perhaps naively, on a more general theme.

\* \* \*

The remarkable advances in the treatment of anemia of the past decade and a half, when contrasted with the yet unscalable obstacles, perhaps justify an attempt at a realistic appraisal of the possibilities and limitations of existing therapy. Today, five general methods of treatment of varying effectiveness and permanence are clearly discernible. Thus, there are substitution therapy for nutritional deficiency or for dysfunction of the endocrine system, chemotherapy, splenectomy and irradiation. Finally, on its own merits and also as a means of preparation for some other form of therapy, there is transfusion.

### SUBSTITUTION THERAPY

Starting with the pioneer clinical observations of Minot and Murphy in 1926, the effectiveness of liver and later of stomach preparations in the treatment of patients with nutritional types of microcytic anemia has become thoroughly established. In this locality, the conditions amenable to such therapy are usually Addisonian pernicious anemia and that of pregnancy. With the further exception of certain rare cases of nutritional macro-

cytic anemia, usually due to intestinal disturbances, all types of anemia fail entirely to respond to such preparations. Valuable contributions to the practical development of the present effective therapeutic products have been made by both university and commercial research groups. Since the amount of active material remaining in the finished product depends on the efficiency of the method of manufacture, it seems unwise and uneconomical for physicians to prescribe products whose potency is defined only in terms of the amounts of tissue with which the manufacturer started his process. The obvious and satisfactory alternative definition of potency in terms of the amount of effective material in the final product is currently described in U.S.P. units for all antianemia remedies accepted by the *United States Pharmacopoeia* or the Council on Pharmacy and Chemistry of the American Medical Association.

Active commercial preparations of the liver for oral or parenteral use, and of the stomach or of the stomach and the liver potentiated by incubation for oral use, are available. Because in the average patient the effectiveness of a given liver preparation is from sixty to one hundred times as great when given parenterally as when taken by mouth, the former route provides a distinctly more economical manner of administration. The small volume of material to be injected (several commercial preparations contain at least 15 U.S.P. units per cubic centimeter) and the infrequency of injections required for maintenance (15 or 30 U.S.P. units at intervals of two weeks or a month) render the use of any oral preparation a doubtful policy, from the point of view of both effectiveness of treatment and convenience or expense to the patient. Few patients conscientiously persist in taking considerable amounts of medicine by mouth two or three times a day for long periods after they consider themselves perfectly well. Because a definite but unpredictable num-

\*The Annual Oration delivered at the annual meeting of the Massachusetts Medical Society, Boston, May 26, 1942.

†Professor of medicine, Harvard Medical School; associate director, Thorne Electric Memorial Laboratory; director of Second and Fourth (Harvard) Medical Services, Boston City Hospital.

ber of patients in severe relapse fail more or less completely to respond to products administered orally in usual amounts, it is certainly unwise to initiate treatment by any other method than that of parenteral therapy, usually in terms of multiple *U.S.P.* units daily for the first few days. A similar indication is provided by patients with pronounced neural manifestations. With exceedingly rare exceptions, the present purified and concentrated preparations seem to be as effective as the older and cruder products in the treatment of pernicious anemia and its neural complications. A practical point in the early detection of the onset of remission is to determine the reticulocyte percentage on the fifth and seventh days after therapy with liver or stomach preparations has been instituted. In the response of anemic patients, the increase of the reticulocytes is so much more striking than the change in red-blood-cell or hemoglobin values in the first week that, relying only on the latter, the physician may fail to realize that the response has already begun.

Although liver extracts, especially the less highly purified products, are to some extent sources of various members of the vitamin B complex, these are apparently unessential to the remission induced by the active hematopoietic principles of liver. The treatment of pernicious anemia by vitamins is thus a waste of material. Whereas it is true that large amounts of whole or autolysed yeast may, under experimental conditions, cause detectable improvement in pernicious anemia, it is probable that these agents act only indirectly through their power to induce the formation of liver extract in the body. In actual practice, they are without significant value compared to the efficiency of active liver or stomach preparations, and their use is an additional burden on the patient and his pocketbook. Whether or not vitamin C is an effective agent in the rare macrocytic anemia of scurvy remains to be proved. Since fruit juice containing vitamin C has been shown to be capable of causing blood regeneration in such patients, it can be readily employed in any case whether its activity depends on ascorbic acid or other factors. Today, the sole essential for maintaining continued and complete remission in pernicious anemia is the exhibition of sufficient amounts of active material by a single route at regular intervals. The advances of the last fifteen years have almost deprived the adjective "pernicious" of any real meaning. Indeed, it is a puzzling question whether the diagnosis "pernicious anemia" should appear on the death certificate of a patient who by adequate treatment has been maintained through many years with a normal blood count and who has died of causes entirely unrelated to his original anemia.

The effective use of iron in the treatment of anemias now known to be hypochromic is older than the record of history. Its latest and presumably permanent reappearance on the platform of sound therapy dates from the independent observations of Barkan and Meulengracht, in 1923, in Europe. They abandoned the small amounts of iron advised by theory and used dosages comparable to those effectively employed today. It is now known that almost any sort of iron, if orally administered in a finely divided form or as a nonirritating iron salt, is effective in the treatment of hypochromic anemias in which loss of hemoglobin and consequently of iron has been brought about by bleeding, pregnancy or growth. Observation shows that ferrous compounds are in general more effective than ferric. The dosage of ferrous compounds is about 5 gr. three times a day, best given just after meals to avoid gastric irritation. Many injections of iron have been made without much effect because of the minute amount of iron in these often expensive and elegant ampules. Today, it is recognized that it is very rarely necessary to promote hemoglobin regeneration by injections of iron. If, however, because of failure of oral therapy in adequate dosage, such a procedure is required, suitable preparations—sterile solutions of ferric ammonium citrate or ferrous gluconate—are available.

The indication for the use of iron is a low hemoglobin concentration in the red blood cells or a low color index. Unfortunately, the hypochromic anemia of chronic infections and that of the so-called "Mediterranean anemia," although possessing these characteristics, do not respond to iron. Experimental animals with hypochromic anemia that have failed to respond to iron are often relieved by vitamin B<sub>6</sub>, but this is not true of patients, at least in my experience. In growing experimental animals, carefully deprived of access to copper, it has been convincingly shown that this element as well as iron is essential for relief of the anemia that develops. Some authors have reported a similar use for copper in anemic infants given small doses of iron. There is, however, no convincing evidence that patients failing to respond to usual doses of iron will respond to the addition of copper. Liver and stomach preparations are useless. Moreover, indiscriminating polypharmacy obscures the effective agent and may lead to needless and expensive types of maintenance therapy. Iron, therefore, appears to be the only agent of practical importance in the treatment of hypochromic anemia.

Patients with myxedema commonly have some degree of hypochromic and occasionally macrocytic anemia, especially if gastric anacidity is pres-

it. Hypopituitary syndromes are also sometimes associated with anemia. Treatment in both conditions depends on suitable endocrine therapy, and may be accelerated by the use of liver extract or oil, according to the character of the anemia.

### CHEMOTHERAPY

Chemotherapy, although primarily employed for the infection itself, is more than incidentally a means of combating hemolytic anemias, such as those due to the streptococcus or to the malaria parasite. The unrecorded experiments of Indians with Peruvian bark long antedate modern chemotherapy. The latest advance is that initiated by Domagk in 1933 by the discovery of the bacteriostatic action of a sulfonamide in experimental streptococcal infections. To discuss in detail the use of sulfonamides or quinine is obviously beyond the scope of these remarks. Chemotherapy may also be of value as an accessory in the treatment of blood dyscrasias of which an infection is an important complication. Thus, the advent of an infection of the respiratory or urinary tract may even be fatal in a patient with severe anemia otherwise easily amenable to therapy. The signs of infection, however, may be falsely simulated in a patient with a hemoglobin level of less than 25 per cent by a fever of 1 or 2°F. that may be entirely due to the anemia; even higher temperatures may result when an active hemolytic process is present entirely without infection. For the local tissue necrosis and secondary infection encountered, usually in the oral cavity, in agranulocytosis, aplastic anemia or leukemia, especially the monocytic variety, the relatively small experience available already indicates a value for the sulfonamides. Their utility consists in holding in check the invasion of the infection until other remedies may have an opportunity to act on the underlying blood dyscrasia.

It seems clear that in general, as in the presence of primary infections associated with leukopenia, the possibility of further depression of the granulocytes is not so great a risk as the danger from the infection when uncontrolled by chemotherapy. Sulfonamides, like certain other cyclic compounds, have caused acute hemolytic anemia, leukopenia, thrombopenic purpura and aplastic anemia. Fortunately, such undesirable results occur in only a very small percentage of cases, and their manifestations can usually be prevented by early detection. Because the chance of such an occurrence is small, one should never hesitate to administer these valuable drugs when a serious infection presents a clear indication for their use. On the other hand, the widespread and indiscriminate employment of the sulfonamides for trivial infections may well produce from only a small percentage incidence a

considerable number of hematologic complications, immediate or remote.

### SPLENECTOMY

In 1911, Micheli observed the benefit of splenectomy in a case of acquired hemolytic jaundice, and in the next two years, Eppinger and Banti independently reached the conclusion that it was a logical and successful procedure in congenital hemolytic jaundice. In this community, Dameshek has recently done a service by calling attention to various types of acquired hemolytic jaundice and by re-emphasizing the therapeutic value of splenectomy in some of them. The success of splenectomy in such anemias depends on the predominance of pathologic blood destruction in the spleen. In congenital hemolytic jaundice, the red blood cells almost invariably exhibit some increase in fragility in hypotonic saline solution, and the spleen is usually large and the pulp engorged with blood. A successful splenectomy is almost always dramatically effective in returning the patient's blood values to normal. If necessary, as a preliminary to operation, rapidly repeated transfusions should be given to bring the hemoglobin level to at least 50 per cent of normal. Although this may be difficult in the face of a crisis of rapid blood destruction, splenectomy not only promptly abolishes this phenomenon but also, by extrusion of blood from the spleen during operative manipulation, provides an autotransfusion, often immediately raising the hemoglobin level by 15 per cent or more. Consequently, splenectomy should not be unduly delayed.

In patients with acquired hemolytic jaundice, a term that includes several distinguishable acute and chronic forms of disease, a generalization concerning the effect of splenectomy is impossible. Perhaps, however, it can be stated that after certain causes of hemolytic anemia that are amenable to other forms of treatment have been excluded, splenectomy is likely to be beneficial if the fragility of the red blood cells in hypotonic saline solution is significantly increased and if the spleen is distinctly enlarged. Splenomegaly alone, however, provides no guarantee of success for splenectomy. Before the procedure is undertaken, the duration and nature of the hemolytic process should be carefully studied. Thus, in acute cases, the history may reveal exposure to hemolytic compounds, such as phenylhydrazine, sulfanilamide and arsine, or in other cases, dark urine (hemoglobinuria) after exposure to cold or after sleep. A blood culture or film may demonstrate septicemia due to bacteria or malaria parasites. Exposure to pure carbon dioxide causes anoxic microscopic sickling in sickle-cell anemia, and in paroxysmal nocturnal

hemolysis. A positive serologic test for syphilis and hemolysis on chilling (Donath-Landsteiner phenomenon) confirm the diagnosis of paroxysmal hemoglobinuria *e frigore*. Such patients are not suitable for splenectomy. In other patients, auto-agglutination of the red blood cells has been remarked; Dameshek has found hemolysins in the serum independent of isohemolysins in a certain group of cases. Bone-marrow biopsy or splenic puncture may disclose other causes of acquired hemolytic anemia, such as aleukemic leukemia, Hodgkin's disease and agnogenic myeloid metaplasia. Suffice it to say that if the conditions enumerated above, which are amenable to other types of therapy, can be excluded and if severe hemolytic anemia with acholuric jaundice and manifest signs of active blood regeneration persist for some days despite frequent transfusions, splenectomy may be indicated, at least as a means of somewhat reducing excessive blood destruction and, possibly, of abolishing it.

It is to be emphasized that the expectation of success from splenectomy in so-called "acquired hemolytic jaundice" is quite different from that in the congenital condition, and as in thrombopenic purpura, although splenectomy is the only therapy likely to be effective, its success is far from certain. Likewise, splenectomy in Banti's syndrome, in which the hypochromic anemia is probably to a considerable extent due to chronic and often occult bleeding from varices, is not always of benefit. The operation is often technically difficult because of the adherence of the spleen to nearby structures, and only when the obstructing vascular lesion is confined to the splenic vein is there considerable certainty of complete relief. Unfortunately, some type of hepatic cirrhosis is most frequently responsible for "chronic congestive splenomegaly," the highly appropriate descriptive term for Banti's syndrome that was coined several years ago by a Boston physician, the late Dr. Ralph C. Larrabee.

#### IRRADIATION

Irradiation by roentgen rays or radioactive phosphorus is today considered the chief weapon in treating leukemias and related conditions. Yet, although in discussions of such treatment great attention is paid to the number and character of the leukocytes, a disabling and frequently fatality-determining feature of leukemia is the anemia that sooner or later appears. Indeed, the problem in the irradiation of leukemias is not so much how to effect a reduction in the number of white blood cells as how to increase the number of red blood cells (or platelets). Since it is usually considered unsafe to apply x-ray therapy in the presence of severe anemia, preliminary transfusions to bring

the hemoglobin to a level of at least half the normal value are indicated.

The justification for discussing the use of irradiation, a highly technical procedure requiring special apparatus and experience, is that the best results from such therapy in leukemias can be obtained only when collaboration between clinician and roentgenologist is close and intelligent. It is assumed, for purposes of discussion, that the anemia in the leukemias is due to a considerable extent to the mechanical inhibition of normal red-cell production in the marrow cavity by overcrowding with immature leukocytes. In other cases of myelophthitic disease, the bone marrow is invaded by the cells of metastatic carcinoma or is replaced by lipoid-bearing cells or by fibrous or osseous tissue, as in osteosclerotic anemia. Because the cells of most metastatic carcinomas, like those of fibrous or osseous tissue, are presumably insensitive to irradiation, no improvement of the red-cell level is to be expected from irradiation in such cases. Accordingly, when there is doubt regarding the character of the disturbance in the marrow, sternal biopsy is indicated before one decides whether x-ray therapy is to be given.

Although the use of x-rays in the treatment of leukemia was introduced by Senn as early as 1903, it is even now difficult to choose the most suitable procedure and amount among the variety of methods and dosages that have been and still are employed. Experience agrees, however, that in acute leukemias the process is inherently of such a kind or its rate of progress is so rapid that irradiation is not only useless but detrimental. By contrast, in the management of chronic leukemias, especially the myelogenous, the skillful use of irradiation is frequently a means of providing a comfortable and useful existence during months or even years.

In the treatment of chronic leukemias, a trend can be observed toward the use of small amounts of irradiation applied to the body generally, in contrast to heavy local exposure of obviously enlarged organs, such as the liver and spleen. Because the abnormal cells in chronic leukemia diffusely invade the active bone marrow, this tendency seems logical. Since, however, it is never possible to gauge with accuracy the effect of a physical agent on a complex biologic system, overdosage of the entire bone marrow is most surely avoided by exposure of only a portion of it to the action of x-rays at one time. It is desirable, whenever possible, to avoid heavy local irradiation which, despite a selective effect on immature cells, injures all cells—even those of normal tissues. We have observed enlargement of the spleen to remain substantially undiminished after relative

doses of x-ray therapy applied locally, only to the organ later diminish in size, apparently a result of repeatedly administered small amounts of general irradiation. If an interval first of a few days and later a week or two allowed to elapse between exposures of a part of the body to no more than 75 to 100 r, leukocyte count preceding each contemplated irradiation becomes a good measure of the effects of previous therapy and thus tends to prevent overage. Finally, observation suggests that significant increase of red blood cells may not begin for several weeks after sufficient irradiation to cause marked lowering of the leukocyte count. Because seemingly within the somewhat narrow range dosage between suppression of leukocyte production in the marrow and suppression of erythropoiesis, that the effects of irradiation are most beneficial, it is desirable to proceed with sufficient deliberation to allow for observations on the production of both types of cells.

The use of radioactive phosphorus, logically introduced in the treatment of leukemias by Dr. H. Lawrence, of San Francisco, is still under evaluation. Nevertheless, it seems probable from the results already reported from several localities that radioactive phosphorus is not the final answer to the problem. The impression gained by one who, it should be said, has had no personal experience with the method is that it represents, like x-ray therapy, a form of irradiation theoretically more selective in its effects on leukemic cells and simple to administer. To my mind, however, it has the theoretical objection that all the hematopoietic organs are exposed simultaneously to irradiation. Nevertheless, eminently satisfactory results have been obtained with radioactive phosphorus in the treatment of chronic leukemias, especially those classified as myelogenous. It is still too early to be certain that such effects are superior to those obtained with modern x-ray treatment. In the management of acute leukemias, leukemic leukemias and leukemias in which severe anemia persists with or without previous x-ray treatment, radioactive phosphorus appears to be able to cause benefit as consistently as any other form of irradiation does.

#### TRANSFUSION

The final therapeutic aid in the treatment of anemia is blood transfusion. Today, the use of citrated blood, possessing as it does the important advantages of comparative leisure in collection and administration and convenience in transportation and storage, is the method of election. In spite of theoretical objections, fresh citrated blood apparently possesses no practical disadvantages compared with unaltered whole blood. Increased care in the

preparation of glassware, tubing and citrate solutions has eliminated many of the febrile reactions to such transfusions. Since, with anemia, the hemoglobin content of the recipient's blood is always reduced, whole blood rather than fresh, preserved or reconstituted plasma is the medium of choice. Thus, in the treatment of anemias, the plasma serves largely as a vehicle for the conveyance of red blood cells. Were it possible at present—when war places a premium on the collection of plasma—to discover a means of preserving the discarded red blood cells intact over relatively long periods, this by-product of emergency activity would no longer largely be wasted.

In the treatment of anemia, blood transfusion plays a significant, although entirely passive, role. Since the hemoglobin concentration in the circulating blood is increased, the blood is better able to carry oxygen from the lungs to the body tissues. With one unimportant exception, there is no evidence that transfusion has a stimulating action on the bone marrow, so far as the production of red or white cells or platelets is concerned. The exception is that, as a result of the eventual destruction of the transfused red blood cells, iron and possibly other materials necessary for new red-cell production may slowly be made available. This delayed and feeble action of transfusion, demonstrable only in hypochromic anemia, can scarcely compare with the effectiveness of the oral administration of a few grams of iron. On the other hand, there is no evidence that transfusion has any depressing effect on the bone marrow unless it raises the hemoglobin above normal values. Transfusion never passively raises the recipient's leukocyte count for more than a few minutes, but may, probably by introducing platelets, cause a cessation of bleeding in thrombopenic purpura for several hours or a few days. The effect of transfusion on bleeding in hemophilia is by virtue of the introduction of a clot-accelerating agent, probably enzymic, associated with the plasma globulins.

Transfusion provides a valuable and sometimes lifesaving procedure in the treatment of anemia, for it may give time for other methods of treatment to become effective or for spontaneous improvement to occur. Thus, patients with sufficiently low hemoglobin values may die before the effect of liver extract or iron therapy takes place. The use of transfusions as a means of carrying patients through hemolytic crises or of preparing them for splenectomy or for x-ray therapy has already been mentioned. In patients with a temporary suppression of red-cell production, as in benzol poisoning, adequate hemoglobin levels may be artificially maintained until Nature initiates new blood formation in the bone marrow. Finally, in aplastic anemia, or with aleukemic

leukemia, a reasonably comfortable existence may sometimes be prolonged for many months by the skillful use of transfusions alone.

For the effective employment of transfusions, two conditions must be met: blood must be readily available and of the proper type; and the technic of the transfusions must be satisfactory and their use judicious. The availability of suitable blood in urban communities is largely an economic question. In fact, the cost of repeated transfusions often becomes prohibitive for many persons able to employ private physicians. The relative difficulty of drawing blood in the past and the comparative rarity and dramatic setting of the procedure have much to do with the present high cost of a pint of blood in many localities. Rarely, today, does the professional donor from whom blood was formerly drawn by an incisional approach to his veins have this unnecessary cause to raise the value of his contribution. The solution, like that of other price situations depending on the economics of supply and demand, will probably come through extension of the organization and invention that have produced the blood bank, the volunteer-donor registry and the emergency blood-procurement service. It is logical to replace the iron lost by the donor by means of a two weeks' course of orally administered ferrous iron.

Time does not permit a discussion of the problems of blood typing except to say that mistakes can most certainly be avoided by the use of typing serums of high agglutinating titers. The relatively rare possibility of the development of anti-Rh agglutinins by the recipient during pregnancy or as a result of previous transfusions has recently been disclosed by the brilliant work of Landsteiner, Wiener, Levine and their associates. A final direct test involving incubation of the donor's cells in the recipient's serum for half an hour, with subsequent microscopic inspection, will almost certainly detect incompatibilities, although to determine their precise nature may require special methods. However, despite the use of compatible blood and of scrupulous care, some unknown quality of certain patients with anemia due to other causes than blood loss renders mild or even severe febrile reactions likely to occur.

From the recipient's point of view, the technic of transfusion includes skillful venipuncture with a short-bevel needle of small caliber that tends to minimize injury to the vein. The blood should be run in slowly, especially in severely anemic patients, to avoid a sudden increase in blood volume, which may overburden an already hard-pressed circulation. The alkalinization of the recipient's urine with 12 gm. of sodium bicarbonate, given an hour or two before transfusion, prevents the precipitation of hemoglobin in the renal tubules

if, for any reason, hemoglobinuria results from the transfusion. As a "biologic test," it is desirable to inject not more than 50 cc. of blood in the first half-hour and to watch for symptoms and signs of a reaction. In the management of patients with anemia, the fact that subsequent transfusions may be required should always be borne in mind. Although cutting down on the recipient's vein and its ligation after transfusion are rarely necessary, this unfortunate practice still exists. As a result, patients whose veins have been destroyed by several previous transfusions may present a serious technical problem. Fortunately, in such cases, it is sometimes possible to use the femoral vein or, according to the recent work of Tocantins, to infuse blood directly into the marrow cavity of the sternum. Aside from its physiologic benefit to the patient, the facile performance of transfusion has a desirable psychologic effect in dispelling the dramatic or ominous connotations of the method in the mind of the layman.

If the use of transfusions is to be fully effective, the objective to be obtained should be kept clearly in mind. For example, if the hemoglobin level of a patient with pernicious anemia is considered dangerously low for the interval of a few days before parenteral liver-extract therapy becomes effective, a single transfusion often suffices. On the other hand, in a patient with a type of anemia in which improvement may be long delayed or may never occur, transfusions repeated at appropriate intervals should be given to raise the hemoglobin and to maintain it at a level compatible with moderate activity in convalescence or at light work. It is a waste of precious and potentially useful weeks or months of such a patient's life if, owing to parsimony in the number of transfusions, he is needlessly confined to bed or home.

\* \* \*

It is a truism that proper treatment depends on accurate diagnosis of the type of anemia. Perhaps it is not so well known that this is often impossible from the examination of the blood alone but requires, as in any other field of medicine, careful history taking and physical examination and special laboratory examinations. The final proof of the correct diagnosis of nutritional-deficiency anemias is an orderly hematopoietic response to substitution therapy at the expected time. Because certain types of anemia may masquerade as cardiac, renal, nervous or even orthopedic conditions, a correct determination of the patient's hemoglobin level should be as routine a procedure as the performance of a urinary examination. Even when one is dealing with an incurable ailment, therapy effectively directed at an associated anemia may sometimes bring reward to both patient and physician.

## FAMILIAL NONHEMOLYTIC JAUNDICE\*

## Report of a Case with Liver Biopsy

JOHN J. CURRY, M.D.,† TIBOR J. GREENWALT, M.D.,‡ AND RUSSELL J. TAT, M.D.‡

BOSTON

UNDER the designation "familial nonhemolytic jaundice," Dameshek and Singer<sup>1</sup> recently reported a group of cases of mild acholuric jaundice occurring in several members of two families. Although congenital hemolytic jaundice as at first suspected in these cases because the in den Bergh reaction in the blood was "indirect" and the urine contained no bile, this diagnosis was conclusively ruled out because none of the evidences of increased blood destruction (spherulosis, increased hypotonic fragility, increased urobilinogen output and so forth) were present, and there was no evidence of increased activity on the part of the bone marrow (polychromophilia, reticulocytosis, high platelet count and so forth). On the other hand, organic hepatic disease seemed unlikely in view of the lack of progression of jaundice over a period of years and use of the various tests for liver function were negative. That the condition was due to a specific functional disturbance in the excretion of indirect bilirubin from the blood by hepatic cells was indicated by the bilirubin-excretion test, which invariably showed a marked retention of injected bilirubin. It was believed by these authors that the disease itself was organically normal, especially since L. J. and Lowenstein<sup>2</sup> had discovered families of affected rats with an identical picture in histologic studies of the livers were uniformly negative. Although Dameshek and Singer were unable to perform biopsies of the liver in their cases, Krarup and Roholm<sup>3</sup> recently reported of a similar or identical condition ("icterus juvenilis"<sup>4</sup>) in which aspiration biopsies of the liver were negative. In none of the cases<sup>5</sup> were biopsies of the liver reported. In present investigation, there was opportunity for a detailed study of a patient with the features of the familial nonhemolytic condition. A biopsy of the liver was performed at operation. In addition, it was possible to study sections of the spleen, which had been removed previously under the impression that the disease was one of familial hemolytic jaundice. The

results of these studies, which showed a normal histology of both the liver and spleen, are the subject of the present report. The lack of response to splenectomy again indicates the necessity for differentiating the disorder from hemolytic jaundice.

## CASE REPORT

P. M., a 50 year-old divorced Irishman, was admitted to the Third (Tufts) Medical Service of the Boston City Hospital on May 25, 1941 in a state of marked disorientation, possibly alcoholic.

Physical examination revealed a well developed and well nourished man with marked jaundice of the skin and scleras. There was no abdominal tenderness or spasm, the liver was not palpable, and there was a well healed longitudinal incision in the left upper quadrant. There were no abnormal neurologic signs, and the remainder of the physical examination revealed no significant abnormalities.

Under symptomatic treatment, the state of mental confusion cleared completely in 2 days, at which time the following history was elicited:

The patient and an older sister had been yellow since birth. The parents and three other siblings had never been jaundiced. A paternal cousin was jaundiced at birth, but the icterus soon disappeared. The patient had two children, neither of whom had ever been jaundiced, and there was no other history of jaundice in the family.

Because of their yellow color the patient and his sister shunned all social contacts, and were frequently ridiculed as "Chinks" by neighbors and even by members of their own family. This resulted in the formation of a close emotional attachment. As children, both developed normally. Neither had ever had pruritus or undue fatigue, nor had they noticed dark urine or clay-colored stools. They had never shown any gastrointestinal symptoms and the jaundice, although varying somewhat in intensity from time to time, had never been related to food intake. Since the age of 18, the patient had been a moderate whiskey drinker, bouts of drinking seemed to increase his jaundice.

The first admission, in May, 1918, was at another hospital, where the patient was admitted for study of his jaundice. The notation was then made that he had contracted syphilis 5 years previously, and had received oral mercurial therapy for 6 months. Positive physical findings at that time were icteric skin and scleras, splenomegaly (?) to 2 cm. below the left costal margin, and the presence of a penile scar. The blood Hinton reaction was positive. The laboratory data are presented in Table 1. The diagnoses were hereditary jaundice and syphilis. The patient was discharged to the Outpatient Department, but failed to attend.

He was next seen in August, 1923, at the Boston City Hospital, this time because of "nervousness." Physical examination, except for jaundice, was entirely negative. The laboratory data are shown in Table 1. A diagnosis of hereditary jaundice was also made.

†Was aided by a grant from the Chilton Fund, Tufts College.

‡Present Third (Tufts) Medical Service, Boston City Hospital, fellow in hematology, Boston Dispensary and Joseph H. Pratt Hospital.

The patient was readmitted in September, bleeding profusely from self-inflicted slashes of the wrists and neck. He revealed that he had "double-crossed" his jaundiced sister in a real estate transaction and, in a state of marked depression, had attempted suicide. Physical examination revealed lacerations of the neck from ear to ear, and several smaller lacerations of both wrists. Except for jaundice, no physical abnormalities were noted. On entry, the patient presented a picture of marked hypochromic anemia due to blood loss. Extensive laboratory studies were performed (Table 1). A diagnosis of atypical familial acholuric jaundice was made, and splenectomy was recommended.

On November 19, when the blood had returned to normal, splenectomy was performed. At operation, the spleen

Liver-function tests showed no bromsulfalein retention after 15 minutes. Another determination showed 20 per cent retention in 15 minutes. The hippuric acid excretion was 3 gm. Bilirubin-excretion tests were performed on three occasions, but the results, although indicating marked retention, proved unsatisfactory, owing to the unusually high fasting-serum-bilirubin level. The prothrombin time was normal. The daily fecal urobilinogen output ranged from 8 to 25 mg. (normal 50 to 200 mg. per day). This was unaltered by the daily administration of 1.2 gm. of sodium dehydrocholate (Decholin) intravenously.

On x-ray examination, the patient's chest and skull showed no abnormality. The gall bladder failed to visualize after oral cholecystography. Intravenous cholecysto-

was found to be normal in size and consistence. The jaundice became somewhat less intense following operation.

During convalescence, the patient developed auditory hallucinations and was committed to the Boston State Hospital, where he remained for 14 years as a case of manic-depressive psychosis, depressed state, and where his stay was uneventful.

After discharge, he was employed as a restaurant worker, and enjoyed good health until admission to the Boston City Hospital.

Examination of the blood showed a red-cell count of 5,020,000 with a hemoglobin of 14 gm. (90 per cent), and a white-cell count of 13,900 with 1,900,000 platelets and 1.2 per cent reticulocytes. The hematocrit was 47 per cent, the mean corpuscular volume was 94 cu. microns, the mean cell diameter was 8 and the mean cell thickness was 1.87 microns. The blood smear showed 54 per cent polymorphonuclears, 34 per cent lymphocytes, 3 per cent monocytes, 7 per cent eosinophils and 2 per cent basophils, with occasional target cells and Howell-Jolly bodies. Rouleaux formation was normal. The red-cell fragility to hypotonic saline solutions began at 0.44 and was complete at 0.12 per cent. An aspiration biopsy of the sternal marrow was negative.

Numerous urinalyses revealed no bile or increase in urobilinogen content. The serum bilirubin ranged from 3.4 to 12.6 mg. per 100 cc. in fasting blood samples, and always gave the indirect van den Bergh reaction. The total serum protein was 5.6 gm. per 100 cc., with 3.8 gm. albumin and 1.8 gm. globulin. The blood cholesterol was 240 mg. per 100 cc., with esters accounting for 180 mg. The bile acids (Thannhauser and Ginsburg<sup>6</sup>) were 2 mg. per 100 cc. The blood Hinton reaction was positive.

grams revealed a normally functioning gall bladder. A gastrointestinal series showed a chronic duodenal ulcer, and a barium enema revealed a diverticulum of the sigmoid.

Exploratory laparotomy was performed on August 26, under spinal anesthesia. At operation, the liver was normal in size and consistence. The gall bladder was normal in size, color and thickness of wall, and emptied easily on normal pressure. There were many adhesions between the omentum and the site of splenectomy. A small piece of liver tissue was removed.

Histologic examination of sections of the liver was reported as follows:

The architecture is well preserved. There is a clearly recognizable capsule, and the portal areas, central veins and lobules stand out distinctly. About one third of the portal areas have a slight increase in fibrous tissue and show a moderate lymphocytic infiltration. The smaller branches of the portal vein, the hepatic artery and the smaller tributaries of the biliary system show no evidence of disease. There is no bile stasis, and no dilatation of the bile ducts or bile canaliculi.

The liver cells are well preserved, vary in glycogen content, and contain no recognizable fat. The cytoplasm is granular. There are no giant or necrotic cells. There are no mitoses, and no cells contain alcoholic hyalin.

Pigment is present in the liver cells. There is a very little powdery brownish-green pigment in the liver cells adjacent to the central veins; this does not stain for iron. There is a little iron-containing pigment concentrated about the bile canaliculi in isolated nests of liver cells. There is a third pigment, which is also brown to greenish brown in many liver cells; this is not iron

staining (it is not like the pigment of bile stasis). There is no demonstrable hemofuscin.

The endothelial cells are present, free of pigment and inconspicuous.

There is no edema, and no thrombosis or hemorrhage.

The sections of the spleen removed in 1923 were also viewed. The result of microscopic study was: "The spleen shows reticulum-cell and endothelial cell hyperplasia, leukocytosis, eosinophilia and moderate hemosiderosis."

Laboratory studies performed on the patient's sister showed a red-cell count of 3,940,000 with 76 per cent hemoglobin, and a white-cell count of 7250, the serum proteins were 7.5 gm. per 100 cc., the albumin being 5.2 g. and the globulin 2.3 gm. The red cell fragility to isotonic saline solution began at 0.40 and was complete at 0.32 per cent. The serum bilirubin was 11.9 mg. per 100 cc., and the van den Bergh reaction was indirect. The blood Hinton reaction was negative.

### DISCUSSION

All the characteristic features of familial non-hemolytic jaundice were present in this patient.

The familial nature of the disease was established by study of the patient's fifty-four year-old sister, who had been jaundiced since birth. She was in perfect health, had no complaints and gave no history of alcoholism. Although she was markedly icteric, there was neither hepatomegaly nor splenomegaly. Laboratory data revealed no anemia and a hyperbilirubinemia of the indirect variety. The blood Hinton reaction was negative.

The nonhemolytic nature of the jaundice was revealed by the absence of anemia, reticulocytosis and bone-marrow hyperplasia, the low fecal urobilinogen and the normal urinary urobilinogen values and, finally, the failure of the patient's condition to respond to splenectomy. In addition, the spleen was grossly and microscopically normal.

The absence of organic liver disease was confirmed by the findings at laparotomy. The liver was grossly normal, and the biliary system intact; microscopic examination of a liver biopsy specimen was within normal limits. Alcoholic and syphilitic liver disease were thus ruled out. Numerous tests of liver function—hippuric acid synthesis, bromsulphalein excretion, cholesterol partition and prothrombin concentration—were within normal limits. Bilirubin-excretion tests, although difficult to interpret because of the high fasting levels of bilirubin in the blood, showed a definite tendency toward abnormal retention. It is significant that although a high level of indirect bilirubin was present in the blood, there was a low output of urobilinogen in the feces; this indicated, without further testing, bilirubin retention.

This case is of further interest because it afforded the opportunity of studying the hematologic changes eighteen years after splenectomy. These

changes have recently been emphasized by Singer, Miller and Dameshek<sup>7</sup> and are well brought out in the case presented. Thus, there was leukocytosis, with lymphocytosis, occasional target cells and Howell-Jolly bodies, increased platelets, increased hypotonic resistance of the red cells and decreased output of urobilinogen in the feces. The excessively low values for fecal urobilinogen were probably due to the summation of the two factors of delayed bilirubin excretion and splenectomy.

In an attempt to increase the bilirubin excretion, sodium dehydrocholate (Decholin) was injected intravenously on two occasions. In the first experiment, 0.6 gm. was injected twice daily for four days, and the stools were collected during this period. In the second, 4.0 gm. was injected in one dose, and stools were collected for the subsequent four days. On neither occasion was there any increase in the fecal urobilinogen. A control patient with normal urobilinogen excretion also failed to show an increase after one injection of 4 gm. of sodium dehydrocholate intravenously.

This patient represents a living example of the necessity for differentiating familial nonhemolytic and familial hemolytic jaundice. Dameshek and Singer<sup>1</sup> have presented detailed data for making this differentiation possible and have stressed the fact that acholuric jaundice and an indirect van den Bergh reaction need not indicate a hemolytic process. In this and other studies, the value of the fecal urobilinogen output for determining the presence or absence, as well as the degree, of increased hemolysis has become increasingly apparent. Splenectomy in the case presented above apparently reduced the degree of bilirubinemia temporarily, probably through its effect on blood destruction. The contrast between the dramatic cessation of jaundice in familial hemolytic jaundice and the results in this case is indeed striking.

The possibility of familial nonhemolytic jaundice should be considered in every case of persistent, relatively mild, nonobstructive jaundice. It is believed that the condition is commoner than the small number of reported cases indicate.

### SUMMARY

A case of familial nonhemolytic jaundice, with biopsy of the liver, is presented. Splenectomy performed eighteen years previously for "familial hemolytic jaundice" failed to alter the course of the disease. The hematologic effects of splenectomy were apparent.

The injection of large doses of sodium dehydrocholate failed to increase the fecal urobilinogen excretion.

The importance of differentiating the familial nonhemolytic condition from congenital hemolytic jaundice is emphasized.

Since this paper was written we have studied four additional cases of familial nonhemolytic jaundice, occurring in three families.

### PILI TORTI HEREDITARIA\*

BERNARD APPEL, M.D.,† AND SALVATORE J. MESSINA, M.D.‡

BOSTON

THE name "pili torti" was first applied by Ronchese<sup>1</sup> in 1932 to a rare developmental anomaly of the hair. He reported the case of a seven-year-old girl, born in Rhode Island, of Italian descent, who was the youngest of eight children and was apparently normal in every other respect except that the teeth were poor and slightly notched, with spaces between them; the hairs on the scalp were dull blond, lank and frizzly, with a wild bushy appearance. The hair had never been cut but broke spontaneously on slight injury at various short lengths from the scalp. Ronchese made numerous interesting and fairly thorough studies of the hair roots and of the hair shaft in various mediums, measured the elasticity and strength of the hair, and examined the hair follicles microscopically. He also discussed the meager previous literature on the subject and came to the conclusion that his case was the second reported in the literature, in which the hair was characterized by fragility and sharp twists on its own axis. He proposed the name of "twisted hairs." His report has been quoted elsewhere in the literature.<sup>2</sup>

Ronchese presented the same case at the Atlantic Dermatological Conference, March 22, 1941, in Boston. During the interval, the patient had been treated only with fairly constant applications of lanolin. Her hair had grown out fairly long, and there was a marked improvement in the general appearance. She was able at that time to dress her hair so that it attracted no attention and appeared quite normal to the casual observer. At a subsequent date, the sister, two years younger than the patient, was examined and showed a similar but much milder condition. There were

no definite areas of alopecia of the scalp, but the hair showed the same tendency to twisting, and there was a moderate degree of alopecia of the outer two thirds of the eyebrows. This patient did not show any dental hypoplasia.

Although recognizing that Ronchese first called attention to this condition in 1932, Sutton and Sutton<sup>2</sup> call the disease "pili torti (Galewsky)." It may be presumed that Galewsky's name was added because he<sup>3</sup> described a knotted condition, which he called "trichonodosis," in 1906.

In 1924, Ormsby and Mitchell<sup>4</sup> presented a case of so-called "atrophia pilorum monilethrix" in a two-year-old girl who was born without hair and whose scalp remained smooth until the age of fourteen months. Subsequently, the hairs resembled the beaded hairs in monilethrix, but on careful examination this appearance was thought to have been due to a twisting rather than to a beading of the individual hairs. In discussing the case, Foerster<sup>5</sup> stated that the condition resembled monilethrix, but that under the microscope the hairs showed twisting without any break. The same case was presented under the title "atrophia pilorum" by Ormsby and Mitchell<sup>6</sup> in 1925. At that time, there had been a marked improvement in the general appearance, the hairs had grown longer, and the former beaded appearance was less apparent; Dr. Ormsby, in the discussion, stated that he had not been able to prove that there was either twisting or actual beading of the hairs but that there was unquestionably a congenital atrophy.

Danforth,<sup>7</sup> in his studies on hair, mentions the twisting of hairs on their own axes. He apparently considers this a fairly normal phenomenon, varying in its degree in different hairs. The twisting causes a series of half turns so that one side of the hair is alternately toward and away from the observer. The length of the hair involved in the twist ranges from one to several millimeters. The greater distance renders the detection of the twist-

ing more difficult. When the twists are closely connected, the hair is given a frizzly character. This twisting, which is apparently irreversible and may even be seen within the follicle, is probably determined by the follicle, perhaps by periodic changes in the functions of the papilla. Danforth is of the opinion that this twisting may have an anthropologic significance. Franchi<sup>8</sup> believes that the condition may be due to endocrine damage acting on the sympathetic nervous system.

Hellier et al.<sup>9</sup> described the first case reported from England. They also apparently erroneously credited this name to Galewsky, but Ronchese<sup>10</sup>

since the authors found that the twisted hairs, when wet, stretched just as far as normal hairs, they conclude that if these hairs were kept damp there would be less risk of premature breaking.

Within the last few years, several other cases have been reported of which Sutton and Sutton<sup>2</sup> present a complete bibliography.

#### CASE REPORT\*

C. F., a 10-year-old girl, was first seen in the Out-Patient Department for Diseases of the Skin at the Boston City Hospital because of an eruption on the face. This was diagnosed as dermatitis venenata, probably

FIGURE 1. Patient's Younger Sister.

*Note that the pili torti hereditaria is relatively slight.*

led attention to his priority in this nomenclature. Hillier and his associates described a two-year-old girl with a fairly typical case, which apparently was at first provisionally diagnosed as alopecia. An interesting observation that they made points more definitely to a predetermined type, characteristically residing in the follicle, as the underlying feature producing the twist in the hair. They epilated with thallium acetate by electrolysis, following which follicular hyperkeratosis was observed; a few months later, when new hair grew in, it still had the characteristic twists. They made x-ray and optical examinations of these hairs and came to the conclusion that the irregularities were not due to any molecular disturbance of the hair recognizable by x-ray diffraction. The tensile strength of hair in their case showed that the normal hairs were about 10 per cent weaker when dry and 25 per cent weaker when wet, which was too far removed from normal. Moreover,

caused by a patent mange cure, which had been applied to the scalp by the mother. With usual soothing remedies and the cessation of the use of the preparation, the dermatitis promptly improved.

The mother stated that the patient had had a peculiar twisting type of hair since birth. It was somewhat worse when she was younger. Bald areas over the scalp and over the eyebrows were present constantly and were very disturbing. For the preceding 2 months, a large area of relative alopecia over the vertex of the scalp had developed. An older brother and a younger sister of the patient had a similar but definitely less noticeable type of hair; only on careful inspection did the twisting become obvious. The hair of these siblings was softer and could be dressed in a less conspicuous manner, but there was the same tendency toward the thin, straight, frizzled appearance, particularly in the shorter hairs (Fig. 1). The eyebrows were quite thinned out in their outer portions. The younger sister showed no changes in the enamel of her teeth. Her general physical condition was normal. The paternal

\*This case was presented at the Atlantic Dermatological Conference, Boston, March 22, 1941.

The importance of differentiating the familial nonhemolytic condition from congenital hemolytic jaundice is emphasized.

Since this paper was written we have studied four additional cases of familial nonhemolytic jaundice, occurring in three families.

### PILI TORTI HEREDITARIA\*

BERNARD APPEL, M.D.,† AND SALVATORE J. MESSINA, M.D.‡

BOSTON

THE name "pili torti" was first applied by Ronchese<sup>1</sup> in 1932 to a rare developmental anomaly of the hair. He reported the case of a seven-year-old girl, born in Rhode Island, of Italian descent, who was the youngest of eight children and was apparently normal in every other respect except that the teeth were poor and slightly notched, with spaces between them; the hairs on the scalp were dull blond, lank and frizzly, with a wild bushy appearance. The hair had never been cut but broke spontaneously on slight injury at various short lengths from the scalp. Ronchese made numerous interesting and fairly thorough studies of the hair roots and of the hair shaft in various mediums, measured the elasticity and strength of the hair, and examined the hair follicles microscopically. He also discussed the meager previous literature on the subject and came to the conclusion that his case was the second reported in the literature, in which the hair was characterized by fragility and sharp twists on its own axis. He proposed the name of "twisted hairs." His report has been quoted elsewhere in the literature.<sup>2</sup>

Ronchese presented the same case at the Atlantic Dermatological Conference, March 22, 1941, in Boston. During the interval, the patient had been treated only with fairly constant applications of lanolin. Her hair had grown out fairly long, and there was a marked improvement in the general appearance. She was able at that time to dress her hair so that it attracted no attention and appeared quite normal to the casual observer. At a subsequent date, the sister, two years younger than the patient, was examined and showed a similar but much milder condition. There were

no definite areas of alopecia of the scalp, but the hair showed the same tendency to twisting, and there was a moderate degree of alopecia of the outer two thirds of the eyebrows. This patient did not show any dental hypoplasia.

Although recognizing that Ronchese first called attention to this condition in 1932, Sutton and Sutton<sup>2</sup> call the disease "pili torti (Galewsky)." It may be presumed that Galewsky's name was added because he<sup>3</sup> described a knotted condition, which he called "trichonodosis," in 1906.

In 1924, Ormsby and Mitchell<sup>4</sup> presented a case of so-called "atrophia pilorum monilethrix" in a two-year-old girl who was born without hair and whose scalp remained smooth until the age of fourteen months. Subsequently, the hairs resembled the beaded hairs in monilethrix, but on careful examination this appearance was thought to have been due to a twisting rather than to a beading of the individual hairs. In discussing the case, Foerster<sup>5</sup> stated that the condition resembled monilethrix, but that under the microscope the hairs showed twisting without any break. The same case was presented under the title "atrophia pilorum" by Ormsby and Mitchell<sup>6</sup> in 1925. At that time, there had been a marked improvement in the general appearance, the hairs had grown longer, and the former beaded appearance was less apparent; Dr. Ormsby, in the discussion, stated that he had not been able to prove that there was either twisting or actual beading of the hairs but that there was unquestionably a congenital atrophy.

Danforth,<sup>7</sup> in his studies on hair, mentions the twisting of hairs on their own axes. He apparently considers this a fairly normal phenomenon, varying in its degree in different hairs. The twisting causes a series of half turns so that one side of the hair is alternately toward and away from the observer. The length of the hair involved in the twist ranges from one to several millimeters. The greater distance renders the detection of the twist-

## TYPHUS FEVER IN MASSACHUSETTS\*

### Report of a Case Contracted in an Out-of-State Endemic Area

JUSTIN E. HAYES, M.D.,† AND CHARLES E. GILL, M.D.‡

NORTHAMPTON AND WESTFIELD, MASSACHUSETTS

THE comparative rarity of the rickettsial diseases, typhus fever and Rocky Mountain spotted fever, in Massachusetts prompted the report of the following case. Although typhus fever is endemic to the extent of about 3000 cases each year throughout the United States, much of the illness is confined to the South Atlantic and Gulf states.<sup>1,2</sup> Very few cases have been reported from the New England states, and only 16 cases have been reported in Massachusetts since 1929,<sup>3</sup> including a series of 10 cases observed at the Beth Israel Hospital in Boston between 1929 and 1932 and reported in 1933.<sup>4</sup> Rocky Mountain spotted fever was first reported in the states east of the Mississippi River as early as 1931, and its prevalence since that time has been confined largely to the South Atlantic states.<sup>5</sup> The cases in the United States have numbered almost 500 annually in recent years. Three cases have been reported in Massachusetts since 1938, and 2 additional cases were reported in Rhode Island in 1937.<sup>3,6</sup>

#### CASE REPORT

A 55-year-old woman was admitted to the Cooley Dickinson Hospital on March 17, 1941, with the principal complaint of fever, first noted on March 12; the temperature was 103 and 104°F., respectively, on March 15 and 16. This patient, a teacher by occupation, had been known to one of us (J. E. H.) for some years, and the past medical history was entirely negative, except for a cholecystectomy in 1938.

Physical examination on admission revealed very little except the presence of fever and an eruption over the abdomen resembling rose spots. On the 2nd hospital day, this lesion covered the chest, neck and face, and a slight hacking cough appeared. Further extension of the rash was noted on the 3rd and 4th hospital days, with spread to the upper and lower extremities. The eruption was maculopapular and confluent in places, very itchy and dullish red, and at first bore some resemblance to measles. Distinct involvement of the palms and soles was noted. The rash persisted for the next 4 days and slowly disappeared by fading and scaling, complete disappearance being noted on the 10th hospital day. Physical examination of the chest revealed a few rales over the left base, and x-ray evidence pointed to congestion in the same area. The temperature from the time of admission ranged between 102 and 104°F. until slow lysis appeared on the 8th hospital day, or 13 days after the onset of fever. The patient was discharged from the hospital on the 14th day after admission, and recent inquiry indicates complete recovery. Supportive treatment was given as indicated.

\*From the Cooley Dickinson Hospital and the Massachusetts Department of Public Health.

†Physician-in-chief, Cooley Dickinson Hospital, Northampton, Massachusetts.

‡State district health officer, Westfield State Sanatorium, Westfield, Massachusetts.

Urinalyses on two occasions revealed a trace of albumin. Repeated examinations of the blood showed a slight reduction in the red-cell count during the course of the illness. The white-cell count fluctuated between 4700 on admission and 8700 on discharge. Polymorphonuclears ranged from 51 to 80 per cent, the lymphocytes ranging from 16 to 48 per cent; the relative lymphocytosis was most marked on admission. The blood Hinton reaction was negative. Blood cultures on the 2nd and 6th hospital days were negative. Stool culture on the 3rd hospital day revealed no organisms of the typhoid-paratyphoid group. Agglutination tests for typhoid, paratyphoid and undulant fever and the Weil-Felix reaction were negative on the 2nd hospital day. These tests were repeated on the 4th hospital day, and the Weil-Felix reaction was positive in a dilution of 1:40. The titer of the reaction increased to 1:400 on the 10th hospital day and fell to 1:80 in September. Isolation of the suspected infectious agent by guinea-pig inoculation of the blood was not done.

The assistance of the National Institute of Health, United States Public Health Service, was secured in the differential diagnosis of typhus and Rocky Mountain spotted fever. A blood specimen obtained on the 11th hospital day was reported positive to the Weil-Felix reaction in a dilution of 1:5120. The complement-fixation test for typhus recently developed in that laboratory was applied and gave a positive test in a dilution of 1:128. Additional specimens were submitted the following September and October, and the most recent titer of the Weil-Felix reaction was noted to be 1:80, the complement-fixation test being positive in all dilutions up to and including 1:512.

Further inquiry concerning the recent travels of this patient revealed that she had left Northampton on February 16, in the company of a fellow teacher, for an automobile trip to Florida. They arrived in Florida on February 26, and the patient resided until March 13 at the home of a cousin. Mild weather enabled her to indulge in considerable outdoor activity, including swimming and picnicking. No particular exposure to ticks, fleas or lice was noted. However, a prominent scabbed area resembling an insect bite was noted in the left scapular region at the time of hospital admission, and this was considered an extraordinary finding by the patient and her companion. The end of their visit in Florida came the day after the appearance of the fever on March 12. This did not prevent the patient's return, although she was obliged to seek medical assistance in Washington on March 15 and 16, when examination revealed a few "spots" on the abdomen and a temperature of 104°F. The remainder of the trip was made by train.

Much diagnostic confusion was created by the unusual clinical features of this case, and typhoid fever was the first illness suspected. The first four days in the hospital brought the development of the rash to a point where a virus or rickettsial illness was considered. The sustained fever, along with the unusual distribution of the eruption over the palms, soles and head, caused the

attending physician (J.E.H.) to suspect Rocky Mountain spotted fever. Subsequent laboratory work confirmed the presence of a rickettsial infection and made the earlier diagnosis of typhoid fever unlikely. Closer study of the epidemiologic features of the rickettsial infections indicated that typhus fever was the more probable diagnosis. The relative rarity of Rocky Mountain spotted fever in the early months of the year and the year-round incidence of typhus fever reinforced this impression. Furthermore, this patient had recently returned from an area of relatively high incidence of typhus fever.

Correspondence with the United States Public Health Service brought further support for the diagnosis of typhus fever. Their assistance was secured in the testing of the serum of this patient by means of the complement-fixation reaction recently developed by Bengston and Topping,<sup>7</sup> of the National Institute of Health. Tests on two occasions were clearly positive. Recent studies from the same source indicate a high degree of specificity for this test.

Since no specific serotherapy was available, only supportive and symptomatic treatment was given this patient. The sulfonamide drugs were not used.

## SUMMARY

The details of a recent case of typhus fever in a Massachusetts resident are presented. It is likely that the infection was contracted in an out-of-state endemic area recently visited by the patient.

In the differential diagnosis, a specific complement-fixation test recently developed at the National Institute of Health was utilized. Isolation of the infectious agent by animal inoculation was not attempted.

The recent prevalence of two common rickettsial illnesses, Rocky Mountain spotted fever and typhus, in the United States and in Massachusetts is briefly reviewed.

## MEDICAL PROGRESS

### VASCULAR DISORDERS OF THE EXTREMITIES

JOHN HOMANS, M.D.\*

BOSTON

#### OBSTRUCTIVE ARTERIAL DISEASE OF LEGS

##### *Clinical Tests for Peripheral Arterial Deficiency*

THE usefulness of the simpler tests in confirming or refuting the results of the history and routine physical examination is discussed by Montgomery, Naide and Freeman.<sup>1</sup> In all vascular deficiencies, an estimate of the reduction of the arterial supply and the amount of the collateral circulation should be made. A rough estimate of arterial blood flow is secured by observation of the color of the toes when the legs are elevated to an angle of 30° for a minute or two (rapid paling is unfavorable; persistence of pinkness is favorable) and when they are depressed (delay in appearance of pinkness followed by rubor is unfavorable;

rapid appearance and persistence of pinkness is favorable).

In connection with the degree of arterial deficiency, the level at which the arteries are seriously constricted or occluded can be discovered by *oscillometry* and by the *histamine test*. After the state of the peripheral pulses in the feet and legs has been learned, the vigor of the pulse wave at various levels should be observed by the use of the aneroid sphygmomanometer. The cuff being firmly applied somewhere in the calf and blown up to a pressure between diastole and systole, the normal excursion of the needle with each pulse beat will be from 1.5 to 3.0 mm. An excursion of 0.5 mm. or only a trace in one leg, as compared with one of 1 or 2 mm. in the other, indicates that a large vessel is occluded at the level tested or higher. Such an observation is frequently made in thromboangiitis obliterans. When pulsations in both feet are absent, oscillometry may call attention

\*Formerly of articles in this series are not available for distribution, but the articles will be published in book form. The current volume is *U.S.A. Progress Annual, 1940* (Springfield, Illinois: Charles C. Thomas Company, 1941) \$4.00.

\*Consultant, Peter Bent Brigham Hospital and Joseph H. Pratt Diagnostic Hospital, Boston.

to a thrombosis decidedly higher in one leg than the other. The presence of a serious occlusion at some particular level may also be noted by the histamine test. Before the test is made, any overlying functional vasoconstriction should be overcome, as by gently warming the skin (with the hands). One performs the test by placing a drop of a 1:1000 solution of histamine acid phosphate on the dry, clean skin, by needling the skin several times through the drop and by feeling for a wheal. Should a wheal fail to appear in three to five minutes, the tissues are so ischemic that an incision at or below the level tested, as for amputation, is unlikely to heal. The presence or absence of a satisfactory wheal low in the leg has useful prognostic significance when the problem is not one of immediate amputation.

The worth of different vasodilatation tests, that is, of the patient's capacity for vasodilatation in response to various stimuli and to sympathetic paralysis (heating the other extremities, heating the body, administering foreign protein, sympathetic procaine block, spinal anesthesia and so forth) is discussed by Montgomery, Naide and Freeman and by Ochsner and DeBakey.<sup>2</sup> In the presence of organic arterial deficiency, these tests demonstrate the capacity of the remaining arteries for dilatation and, in general, the availability of the collateral circulation. In cases of generalized functional vascular constriction, such as is present in cyanotic, sweaty extremities, the tests recognize this state and predict relief by sympathectomy. (It should be noted that the tests may fail in two respects: they do not foretell the result of sympathectomy in improving, over a long period, the nutrition of the feet in the serious arterial deficiencies of both thromboangiitis obliterans and arteriosclerosis, and they may not relax the most serious gross arteriospasm, such as those that are rarely associated with thrombophlebitis and trauma and are subsequently discussed.)

#### *Procedures for Securing Vasodilatation*

Several methods for producing vasodilatation have recently been scrutinized, notably, intermittent venous occlusion and the administration of a number of chemicals. Intermittent venous occlusion, brought up to date through the invention of an automatic apparatus by Collens and Wilensky,<sup>3</sup> appeared capable of calling forth a reactive hyperemia. Observations of de Takats, Hick and Coulter<sup>4</sup> were confirmatory. Recently, Linton et al.<sup>5</sup> have conducted experiments revealing the immediate effects of venous obstruction on the circulation in the dog's leg. Arterial flow was measured by the *Thermostromuhr*, and venous pressures were recorded as well. Venous occlusion (clamping the principal vein) was found to increase

arterial flow to the extremity. The effect was slower, but still impressive, when the arterial supply was deficient. The increased arterial flow was found to be greater the nearer the heart the venous block was made. When a pneumatic cuff was used, each increase in tightness was followed by a rise in venous pressure and a corresponding rise in arterial flow until the tightness of the cuff reached the level of systolic pressure. Linton and his associates believe that dilatation of the venous tree primarily reduces peripheral resistance and thus permits an increased inflow from the arterial side. Possibly, arteriovenous shunts are opened. Increased arterial flow during increased venous pressure, rather than reactive hyperemia after release of the constriction, is perhaps the chief effect of *intermittent venous occlusion*. The research supports the value of the division of the principal vein of a limb when arterial occlusion has occurred.

The vasodilating effect of various drugs has been studied by Abramson et al.<sup>6</sup> They used the venous occlusion plethysmographic method, which measures the total blood flow to a portion of an extremity, and made observations on normal persons and on patients suffering from vascular and mental diseases. Calcium gluconate, Padutin, papaverine, Spasmalgin and thiamine chloride produced a slight increase or none in blood flow to the hand, forearm, leg and foot. Alcohol, stilbestrol and histamine generally increased the flow of blood to the hand only. Intravenous hypertonic saline solution augmented blood flow into the leg in only one third of the trials. This is interesting in view of the report of Silbert et al.<sup>7</sup> that the intravenous injection of 300 cc. of hypertonic (5 per cent) saline solution regularly increases blood flow to the muscles of the calf. The latter observations were recorded by the deep thermocouple rather than by methods measuring the total blood flow. One is left with the impression that increased blood flow, as induced by chemicals, is brief and of little importance.

In this connection, Brown and Allen<sup>8</sup> have devised an apparatus intended to secure prolonged vasodilatation in chronic occlusive arterial disease. Reflex vasodilatation is secured by means of a heating sleeve or boot applied to an extremity other than the one diseased. The authors believe that arteriolar dilatation is the effect chiefly secured.

#### *Use of Tobacco*

Although the smoking of tobacco has long been recognized as an aggravating factor and a cause of progressive circulatory deficiency in thromboangiitis obliterans, some recent observations are enlightening. Mulinos and Shulman,<sup>9</sup> in a study of the rate of blood flow in the hand, found that deep inhalations without smoke caused vasocon-

striction; that so-called "denicotinized" cigarettes caused a vasoconstriction like that produced by real tobacco; that the response to smoking varied greatly in different persons and in the same subject from time to time; that the actual vasoconstriction, when induced, lasted only about fifteen minutes; and that heavy smokers showed active vasoconstriction even when a systemic reaction to smoking did not take place. Hiestand et al.<sup>10</sup> observed that an increase in the pulse and basal metabolic rates usually, but not invariably, occurred in habitual smokers after the inhalation of cigarette smoke. All such observations indicate that tobacco smoking *may*, by causing vasoconstriction, unfavorably influence blood vessels, in any part of the body, that are diseased in some degree. In this respect, they are not especially impressive. The vasoconstrictive effect of tobacco is very brief. Moreover, observations of Sprague and Homans<sup>11</sup> indicate that heavy smokers suffering from thromboangiitis obliterans may benefit clinically (decided improvement in locomotion through relief of intermittent claudication) by abstinence from tobacco in the absence of Buerger's exercises or other such vasodilating influences even after preliminary observations of cutaneous temperatures in the toes have shown that inhalation of tobacco smoke causes no vasoconstriction whatsoever; and their observations confirm the general impression that abstinence from tobacco leads to recognizable clinical improvement only after many months.

Tobacco may conceivably affect the blood vessels in ways other than by vasoconstriction. Moyer and Maddock,<sup>12</sup> in reviewing the subject, recall the older observations of Harkavy, Hebal and Silbert<sup>13</sup> and of Sulzberger and Feit.<sup>14</sup> The last found that a high proportion of those suffering from thromboangiitis obliterans reacted positively to intradermal injections of various extracts of tobacco (even when nicotine was removed) and not to nicotine itself. Harkavy et al. made similar observations on tobacco-smoking patients who had Buerger's disease, with the additional finding that other smokers rarely so reacted. Since there is reasonably acceptable proof that those who have never smoked occasionally suffer from thromboangiitis obliterans, the question arises whether tobacco acts directly or whether it may not rather reinforce the patient's sensitivity to another adverse influence, such as the presence of a dermatophytosis.

#### *Significance of Dermatophytosis*

Thompson<sup>15</sup> suggests that a number of familiar vascular diseases,—namely, thrombophlebitis, phlegmasia alba dolens, migrating phlebitis,

thromboangiitis obliterans and postphlebotic ulcer,—seemingly unrelated, have a common background of "endothelial necrosis, thrombosis and chronic inflammation involving the walls of blood vessels and their adjacent tissues." With these disorders, the dermatophytoses of the feet are invariably\* associated. Drawing a comparison with tuberculosis, he shows how allergic reactions to antigens derived from the fungi may well constitute the basis of these various lesions. From patients suffering with Buerger's disease and various leg ulcers, he has cultivated fungi from which he<sup>16</sup> has secured a powerful antigen. This antigen provokes in the skin of the legs of persons with such diseases (and not in persons free from them) vivid cutaneous reactions following the intradermal injection of infinitely small doses. Thompson's observations are, of course, in the experimental stage.

Whether or not this line of investigation will prove fruitful and whether or not smoking aggravates supposed allergic reactions of this sort, there is no doubt that effective treatment of dermatophytosis and onychomycosis, combined with abstinence from smoking, has proved of great value in the treatment of thromboangiitis obliterans and other peripheral vascular diseases.

#### *Intermittent Claudication*

With the aid of a mechanical device for studying the ability of the muscles of the calf to contract (Hitzrot, Naide and Landis<sup>17</sup>), Freeman and Montgomery<sup>18</sup> have investigated the effect of sympathetic block and sympathectomy on claudication. They found that when a considerable element of abnormal vasoconstriction was present, as indicated by moist, bluish feet and contracted veins, sympathectomy improved the ability of the muscles to work and increased the walking distance. By selecting their cases of both arteriosclerosis and thromboangiitis obliterans on the basis of a favorable reaction to preliminary sympathetic procaine block, they were able to secure a decided improvement in walking. Undoubtedly, the writers prove their point in respect to a favorable effect in selected cases. But that is not to say that one may not see considerable gradual improvement in locomotion as a result of abstinence from tobacco, scrupulous care of the feet and Buerger's exercises (about which combination the writers say almost nothing). Moreover, observations of Wallace and Smithwick,<sup>19</sup> based on a long series of sympathectomies in serious obliterative vascular disease, show that, even in the absence of a favorable reaction to sympathetic block, sympathectomy

\*On a purely clinical basis, yet without proof by the demonstration that pathogenic fungi are present in the skin

causes, over a considerable period, significant clinical improvement (including locomotion) in a great majority of cases.

### VASOCONSTRICTIVE AND VASOSPASTIC DISEASES

In the second edition of their excellent monograph, *The Autonomic Nervous System*, White and Smithwick<sup>20</sup> decline to differentiate classic Raynaud's disease and such allied vasospastic conditions as acrocyanosis. They group together the acute, recurrent vasospasms in the extremities, regarded by most observers as Raynaud's disease, with the continued vasoconstrictions, — in fact, all the sympathetic dysfunctions remediable by sympathectomy. This is not in accordance with the usual practice in this country, the definition of Raynaud's disease being decidedly narrow, and excluding all vasoconstrictions and vasospasms except the recurrent spasms of the digital arteries as a reaction to cold and emotion. In this review, Raynaud's disease, in the sense of a vasospastic disorder causing acute attacks of cyanosis or asphyxia of the fingers (and toes) on a background of reasonable normalcy, will not be considered. Smithwick<sup>21</sup> discusses it fully in a recent review of the sympathetic system.

#### *Acrocyanosis*

This vague term may properly be applied to the very common reddish-blue, moist extremity. It is difficult to discern the borderline between a richly pink, moist hand and a cyanotic, wet one. In each, there seems to be an exaggerated vasomotor tone in the smaller blood vessels, presumably the arterioles. Social conditions, occupation and self-consciousness or the lack of it make some acrocyanoses and hyperhidroses pathologic, others not.

White,<sup>22</sup> in a picturesque account, strongly recommends preganglionic sympathectomy for hyperhidrosis, since he found no effective palliative treatment.

Regarding acrocyanosis as it commonly occurs in girls and young women, a condition worse in the feet of some patients and in the hands of others, no new information is at hand. The rubor or cyanosis is made worse by cold. White and Smithwick<sup>20</sup> point out that ultimately, in occasional patients, Raynaud's phenomenon of acute, recurrent vasospasm may be superimposed. The background of exaggerated vasomotor (constrictor) tone seems to be curable only by sympathectomy. Recently, several related varieties of acrocyanosis have received attention: namely, livedo reticularis and pernio or erythrocyanosis frigida.

#### *Livedo Reticularis*

This is described as a peripheral arteriolar disease by Barker, Hines and Craig.<sup>23</sup> In their cases,

the upper and lower limbs were covered with purplish discolorations having various forms: hence the terms, "livedo racemosa," "livedo annularis" and "cutis marmorata." The disease, an uncommon one, was seen equally often in men and women. The extremities, especially the fingers, toes, hands and feet, were subjectively and objectively cold and sometimes painful. The large vessels and peripheral pulsations were normal.

The livid areas, as these and other writers have observed, are most marked and thickly distributed peripherally, gradually becoming less colored as the trunk is approached. They are very persistent, and any one spot is only momentarily whitened by pressure. Warmth turns them toward red or pink. Even a sympathetic block is powerless to make them disappear. Organic changes — perivascular lymphocytic infiltration and fibrosis — were found by Barker et al. to be present in the arterioles, and in occasional cases, serious gangrene of the toes was noted. No etiologic factor is known. Treatment by sympathectomy is justifiable.

#### *Pernio*

Pernio, erythrocyanosis frigida and many similar names have been given to the condition commonly referred to as "chilblain," in which a state of peripheral cyanosis is complicated by purplish, raised indurations that ulcerate. McGovern, Wright and Kruger<sup>24</sup> give a thorough résumé of the literature and an authoritative account of the disorder. As in Bazin's disease (erythema induratum), the ulcerations occur principally in the legs of girls. But here, the girls are well nourished, even fat, whereas the victims of Bazin's disease are ill nourished and supposedly tuberculous. In fact, Bazin's disease is believed to be a tuberculid, whereas pernio presents no characteristic pathology.

The authors describe 10 cases, with full reports and with sections of some of the ulcers. The disease, which predominated in young women, appeared in the early winter and disappeared in the spring. The patches, at first red, soon became elevated, hard, purple and painful. They then broke down in part, forming chronic ulcers. Angiitis of the small vessels beneath the ulcers was noted. Although the lower legs were involved in this group, others have noticed similar lesions in the upper extremities when these parts were exposed and the legs were not.

Treatment with acetyl-betamethylcholine chloride (Mecholyl) by iontophoresis and protection from cold are recommended. No mention is made of sympathectomy, of which others spoke in a discussion of the communication and which has been used with apparent success (Homans<sup>25</sup>).

### Frostbite

In connection with pernio, the observations of Leriche and Kunlin<sup>26</sup> on frostbite as a "vasomotor and thrombotic disease" are perhaps appropriate. Following various degrees of frostbite, some digits were found to be edematous and blistered, with raised, loosened nails, while others became gangrenous. Even when edema had disappeared and healing had occurred, painful arterial constriction and even intermittent claudication often remained. Such states were helped by repeated sympathetic procaine block. The authors recommend that the early stages of frostbite and chilblain, marked by edema and pain, be treated by sympathetic procaine block. Such treatment, in their hands, rapidly relieved cases in which there was no actual necrosis, and was of benefit to all patients.

### ARTERIAL SPASM AND ARTERITIS

#### Traumatic Arterial Spasm

Gross spasm of a temporary or prolonged sort in response to various stimuli is becoming reasonably well understood. The larger arteries of the limbs are most frequently involved. Foisie<sup>27</sup> has recently discussed this subject and has called attention to Griffiths's<sup>28</sup> work on Volkmann's contracture. As a result of a number of surgical explorations, Griffiths opposes the conception that this crippling results from an acute venous engorgement due to hemorrhage within the muscular aponeurosis. The disorder is commonest after supracondylar fractures at the elbow. Tight bandages and acute flexion have been thought to be aggravating factors. Griffiths holds that weakening or loss of the radial pulse is the earliest evidence that trauma has thrown the brachial artery into spasm. His explorations revealed a local contraction of the brachial artery that transmitted a mere trickle of blood, a finding identical with an earlier observation of Montgomery and Ireland.<sup>29</sup> His best results followed resection of the spastic vessel, but he suggests that, in cases of moderate severity, immobilization and the administration of papaverine may be effective. Stripping the artery has not been successful, nor has sympathetic procaine block.

One should be on the lookout for this lesion when loss of the peripheral pulses and threatened gangrene of some of the digits follow a bullet wound that has not actually divided an artery, or even when they follow such an apparently trivial injury as the insertion of a needle, during venipuncture, into the cubital space.

In this connection, Leriche and Werquin,<sup>30</sup> have recently called attention to the favorable effect of dividing an injured artery or resecting a considerable portion of it, as opposed to ligation in con-

tinuity. The chances of securing an effective collateral circulation are greatly improved by resection, an old contention of Leriche's, especially applicable in war surgery when arteries are likely to be extensively lacerated and thrombosed in complicated wounds. Resection tends to break up reflex vasoconstriction originating in irritation of the arterial wall and favors the development of a collateral circulation.

#### Arteritis

Hoyt, Perera and Kauvar<sup>31</sup> report 3 cases of temporal arteritis, a lesion first described by Horton, Magath and Brown.<sup>32</sup> This unexplained granulomatous, inflammatory disease of the temporal arteries in elderly persons is associated with serious headache and constitutional symptoms of a severity out of all proportion to the local lesion and tenderness, with redness, over the temporal vessels. No underlying causative factor has consistently been noted. In their cases, resection of a portion of the diseased artery relieved pain and favorably influenced the disease, but fever generally continued for several weeks.

#### Arterial Spasm Resulting from Cervical Rib (Scalenus Syndrome)

MacFee<sup>33</sup> calls attention to dilatation of the subclavian artery distal to the point at which it is compressed behind the scalenus anticus muscle. He found 125 cases with vascular symptoms among 360 cases of cervical rib with pressure symptoms (either nervous, vascular or both). In the particular case he describes, the brachial artery was also noted as a hard pulseless cord. Several fingertips of the cyanotic hand were gangrenous. This account recalls a very similar case reported by Cluie<sup>34</sup> as being "acute arterial obstruction from arteritis." A very reasonable explanation of these peculiar findings has been offered by Telford and Stopford,<sup>35</sup> who suggest that irritation of the vasomotor nerves in the lowest cord of the brachial plexus as it passes over the first or a cervical rib is responsible for spasm and subsequent closure of the brachial artery, and it must be supposed that dilatation of the subclavian is part of the reaction. Besides freeing the structures behind the scalenus anticus muscle, the hard, cordlike brachial artery should probably be resected.

#### Arterial Spasm in Thrombophlebitis

The French and German literature since 1934 has contained accounts of arterial spasms that rarely occur with the onset of femoral thrombophlebitis yet may be serious enough to produce gangrene of the leg. The cause of such spasms, as Leriche and Kunlin<sup>36</sup> have suggested, lies in a perivascular irritation that not only throws the

adjacent artery into contraction but sets up a reflex peripheral vasoconstriction, which will be discussed in the section on thrombophlebitis. The onset of phlegmasia alba dolens is often marked by a diminution in the femoral and peripheral pulses. Rarely, all pulsations below the inguinal ligament disappear, the leg becoming white and cold, as if arterial embolism had occurred. Should the spasm persist, gangrene sets in. Should it relax, as it may very suddenly do, the whole leg becomes engorged with blood. Sympathetic block seems to have little influence on the more violent spasms, although it undoubtedly causes the milder ones to relax.

(To be concluded)

CASE RECORDS OF THE  
MASSACHUSETTS GENERAL HOSPITALANTE-MORTEM AND POST-MORTEM RECORDS AS USED  
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

## CASE 28231

## PRESENTATION OF CASE

*First admission.* A sixty-two-year-old single female physician was admitted to the hospital because of fever for a day following an intermittent cough of a month's duration.

Four weeks before entry, the patient had a sore throat followed in a few days by a dry hacking paroxysmal cough. The cough persisted when the soreness in the throat subsided. About a week later, the cough grew worse during the course of another few days of sore throat. The night before entry, the patient had a severe paroxysm of coughing, "wheezing on inspiration like an asthmatic." This was followed by a chill lasting three hours. She felt nauseated but did not vomit. Soreness but no actual pain developed in the right chest and was aggravated by respiration. The next day, fever was noted, and she entered the hospital.

The patient had been in the hospital five times before, with symptoms suggesting cholecystitis and renal colic. Six years before the last entry, operation disclosed right hydronephrosis due to aberrant blood vessels. These vessels were ligated, and a right nephropexy was performed. At a second operation several months later, an acutely inflamed gall bladder with a single stone was removed. These operations afforded complete relief from symptoms. Four years before the last entry, the patient had a sudden attack of severe "anginoid pain" radiating up the left side of the neck and down the left arm. This attack, which began when the patient was in bed, lasted half an hour. Dull pain and soreness remained for about three days after the acute phase. Three years before entry, there was a similar attack. This episode was not preceded by exertion. After this, the patient remained symptom free except for momentary "tight" sensations beneath the sternum "on climbing hills."

On admission, the patient appeared obese and uncomfortable, with a dry hacking cough. The hands were somewhat cyanotic. The lungs seemed clear. The heart was not remarkable.

The blood pressure was 130 systolic, 60 diastolic. The temperature was 102°F., the pulse 110, and the respirations 30.

Examination of the blood showed a white-cell count of 36,000. The blood Hinton reaction was negative. The urine showed occasional red and white cells in the sediment but was otherwise normal. Throat culture grew beta-hemolytic streptococci but no pneumococci. A blood culture was sterile.

A roentgenogram of the chest showed moderate prominence of the lung roots, without definite evidence of pneumonia.

The patient was given sulfadiazine for five days, a maximum blood level of 18 mg. per 100 cc. being attained on the second day. The temperature returned to normal on the third day, and there was a corresponding fall in the white-cell count to normal. The patient was discharged improved on the tenth hospital day.

*Final admission* (two weeks later). The patient remained well until five days before re-entry, when there was sudden onset of chills and fever, with severe shaking and profuse sweating. The fever was intermittent, reaching 104 or 105°F. each day. The right flank and right upper quadrant became tender. There was no headache, nausea or vomiting.

On readmission, the patient was too tired to sit up for examination. A few crepitant rales were audible at the end of inspiration over the left upper chest anteriorly and posteriorly. The heart seemed normal except for a slight systolic murmur at the apex. There was some tenderness in the left lower quadrant of the abdomen, seemingly over the sigmoid and descending colon. Posteriorly, there was tenderness over the lumbar spine and slight tenderness in the costovertebral angle on each side.

The blood pressure was 100 systolic, 60 diastolic. The temperature was 98°F., the pulse 98, and the respirations 20.

Examination of the blood showed a white-cell count of 26,400 with 95 per cent polymorphonuclears, 4 per cent lymphocytes and 1 per cent monocytes; no parasites were seen in stained smear. Agglutination tests for typhoid fever and undulant fever were negative. The nonprotein nitrogen was 41 mg. per 100 cc. The urine showed a + test for albumin and occasional red and white blood cells in the sediment. Urine and stool cultures grew no significant pathogenic organisms.

A roentgenogram of the abdomen showed considerable gas in the colon and a dilated loop of bowel consistent with ileum in the right mid-abdomen. A roentgenogram of the chest showed no definite evidence of pulmonary consolidation or of pleural effusion. A roentgenogram of the left shoulder was negative. An intravenous pyelo-

DR. LYONS: This whole business of hepatitis is a problem of much interest. We studied 68 patients last spring by prothrombin levels and bromsulfalein retention, and found that 20 per cent of those receiving chemotherapy for acute infection developed some evidence of impaired prothrombin time or bromsulfalein retention and that jaundice was not a regular accompaniment. That type of hepatic disturbance remains to be elucidated.

#### CLINICAL DIAGNOSIS

Acute bacterial endocarditis, Type 7 pneumococcus.

#### DR. ROPES'S DIAGNOSES

Pneumococcal endocarditis.

Ureteral obstruction from sulfadiazine crystals.

#### ANATOMICAL DIAGNOSES

Endocarditis, bacterial (Type 7 pneumococcus).

Renal infarction, complete, right kidney.

Splenic infarction, small.

Nephritis, focal glomerular, acute.

Arteriosclerosis, aortic and coronary, minimal.

Operative scars: nephropexy, cholecystectomy.

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: Post-mortem examination did show a pneumococcal endocarditis of the mitral valve. There was a very large vegetation, 2 cm. in diameter, on the right cusp. This had evidently given off emboli, and one of considerable size was found in the right renal artery, so that the right kidney was totally infarcted. There was also an infarct in the spleen. The left kidney was somewhat swollen. It was examined with great care for crystals. None could be found in the pelvis or the ureter on that side. On the other hand, some crystals were seen in the pyramid. These were teased out, but did not look like the crystals of any of the sulfonamides and proved to be urates. The glomeruli in this case were also abnormal. The glomerulonephritis was somewhat uneven in distribution—very marked in some glomeruli and relatively less marked in others. Of course, glomerular involvement can occur with any form of bacterial endocarditis, so that this is perhaps to be regarded as a very diffuse form of so-called "embolic glomerulonephritis" rather than a true diffuse glomerulonephritis.

The coronary arteries were entirely normal, and there was no hiatus hernia; nothing else was found to explain the attacks of anginal pain. The liver was slightly large and mottled, but showed no demonstrable hepatitis.

#### CASE 28232

#### PRESENTATION OF CASE

A forty-three-year-old shipping clerk was admitted to the hospital because of vomiting and associated abdominal cramps.

He was well until about eight weeks before entry, when he was awakened from sleep by severe cramping pain in the upper abdomen. He vomited part of his supper, together with some peanuts that he had eaten shortly before retiring an hour and a half earlier. There was no further difficulty until two weeks later, when the patient was again seized with severe, shooting epigastric cramps and vomited peanuts eaten an hour earlier. The vomiting was spontaneous and was not accompanied by nausea. It relieved the pain promptly. A physician prescribed belladonna and Amphogel, with restriction of the diet. Subsequently, the patient vomited two or three times a week, with associated pain but no nausea as before. He felt weak and therefore stopped working. He was referred to the Out Patient Department, where physical examination was essentially negative. Roentgenograms of the esophagus, stomach, duodenum and small bowel were likewise negative. The patient was advised to continue his dietary restrictions and his medication. In the four weeks preceding entry, the vomiting became more frequent and severe. The patient often vomited greenish bitter fluid an hour or an hour and a half after breakfast and after lunch. In the week before entry, such vomiting and abdominal cramps followed every meal. Small amounts of bright-red blood were spat up after vomiting. The patient lost 20 pounds of weight during the illness.

The appendix had been removed six years before entry. The past history was otherwise irrelevant.

On admission, the heart and lungs were normal. The abdomen showed slight deep epigastric tenderness but no masses or palpable viscera. Rectal palpation was essentially negative.

The blood pressure, temperature, pulse and respirations were normal.

Examination of the blood showed a red-cell count of 4,600,000 with 85 per cent hemoglobin, and a white-cell count of 8700 with 64 per cent polymorphonuclears. The serum protein was 6.5 gm. per 100 cc. The chlorides were 85.6 milliequiv. per liter, rising to 98.5 milliequiv. Gastric analysis showed 8.0 units of free acid and 9.5 units of total acid (fasting), with no appreciable increase after histamine. The stools were strongly positive for occult blood. The urine was normal.

A roentgenogram of the abdomen showed old residual flecks of barium in the lower descending

colon, possibly in diverticulums. There was considerable gas in the stomach. A repeat roentgenologic examination of the gastrointestinal tract showed a normal esophagus and stomach. The second portion of the duodenum was somewhat dilated, and there was slight delay at the junction of the second and third portions of the duodenum. The third portion was poorly filled and included a crater 1 cm. across, with surrounding induration and probable mucosal destruction. There were several intraluminal defects in the left half of the large bowel suggesting either fecaliths or polyps. On the ninth hospital day, an operation was performed.

### DIFFERENTIAL DIAGNOSIS

DR. JOHN R. GRAHAM: The final x-ray pictures have shown us a definite lesion in the third portion of the duodenum, although the first series failed to reveal any abnormalities. It seems to me that a lesion in this situation would adequately explain the symptoms of vomiting and epigastric pain. The ulcerations mentioned in the last x-ray report could explain the positive guaiac test in the stools, although one would have to think that the patient could not have had a strongly positive guaiac test for very long without more anemia than the blood count showed.

DR. GEORGE W. HOLMES: The fact that they had taken a number of films of this area showed that they were interested in it. The obstruction at the lower portion of the duodenal loop where it joins the ileum is obvious in a number of films, all of which show barium delayed at that point. I suspect that this is what they thought was the ulcer. There is also an unusual amount of gas in the small bowel in some of the films. The colon is normal. The stomach, so far as I can see, is normal. From the evidence I have here, one can say only that there was a definite delay in the passage of the barium meal from the duodenal loop into the jejunum. In one film, it looks like an ulcer.

DR. GRAHAM: Between the duodenal loop and the jejunum?

DR. HOLMES: Yes.

DR. GRAHAM: As I have said, I think the lesion explains the symptoms, and my job is to guess the histology of the lesion. It has certain characteristics, which we can learn from the history and the x-ray pictures. The x-ray films tell us that the lesion was ulcerative, that it had an area of induration around it, and that the mucosal pattern of the bowel showed evidence of being destroyed. I think those things suggest the presence of a malignant lesion, probably one arising in the bowel itself. There is evidence, in the history and perhaps in the x-ray examination, that this lesion progressed

rather rapidly. The whole illness lasted only eight weeks, the symptoms and signs growing rapidly worse during the course of the last month. The x-ray films taken at the end of one month of symptoms failed to reveal dilatation or evidence of obstruction or any lesion that could be seen, whereas those taken after two months of symptoms showed definite trouble. Further evidences against an inflammatory lesion were the normal temperature and the normal white-cell count. The x-ray report mentioned the possible presence of polyps in the colon, which suggest that the patient might have had polyps elsewhere, even in the duodenum. Dr. Holmes, however, doubts the evidence of polyps.

I think the main thing to think of in identifying this lesion is whether it was a carcinoma of the duodenum near the junction of the jejunum, or a lymphoma. We also have to think about a peptic ulcer, since an ulcer was definitely demonstrated. It seems to me that the location of the lesion, the low gastric acidity and the duration of the symptoms are distinctly against an ordinary duodenal or peptic ulcer. One would think about syphilis, but they probably would have helped us out with the Hinton report. There was no history of syphilis. Could the condition have been regional enteritis? On the whole, I lean away from an inflammatory lesion and think that the most likely diagnosis is a carcinoma in that part of the bowel. The second on my list is lymphoma, and I shall simply mention in passing the possibility of polyp that has undergone malignant degeneration, the only reason for that thought being the doubtful presence of polyps elsewhere in the intestinal tract.

DR. CHESTER M. JONES: It seems to me that the first x-ray film did not show anything because it was routine. I think that is a fair statement, but I should like to have Dr. Holmes comment on it. Very frequently, unless the radiologist is asked to look for a definite lesion, he may on routine examination overlook a lesion in the third portion of the duodenum. This lesion may well have been there a month before.

DR. HOLMES: I agree with you, and should like to emphasize the fact that clinicians should tell the radiologist what they have in mind before asking for the x-ray report. One does not see things one does not look for.

DR. JONES: I have seen only a small number of cases of cancer of the terminal ileum, upper jejunum or the lower duodenum. With the history, not of epigastric pain but of umbilical pain, one is given the clue. The lesion should lie in the small bowel well below the mid-duodenum, and one has the right to ask Dr. Holmes to look for it.

DR. GRAHAM: One must consider the possibility of a malignant lesion, extrinsic to the bowel, something to do with the pancreas. However, I thought that the directness with which the symptoms were connected with the lesion and the ulceration were against that.

DR. TRACY B. MALLORY: Can you say anything from the x-ray point of view concerning the possibility of pancreatic tumor?

DR. HOLMES: I think it is a decided possibility; narrowing and obstruction in that part of the duodenum not infrequently are due to cancer arising in the pancreas. The absence of a gross deformity of the duodenal loop does not rule out cancer of the pancreas. I used to think a deformed loop was necessary. But that is not so.

#### CLINICAL DIAGNOSIS

Duodenal cancer?

#### DR. GRAHAM'S DIAGNOSIS

Carcinoma of duodenum.

#### ANATOMICAL DIAGNOSIS

Carcinoma of pancreas, invading duodenum.

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: This patient was explored, and a localized tumor was found in the pancreas in about the midportion. It had invaded the duodenal wall and had produced a small papillary mass in the duodenum, but no ulcer that I could find. A gastroenterostomy was done, and a biopsy of the pancreas showed perfectly normal pancreatic tissue. However, the patient did not long survive gastroenterostomy, and at post-mortem examination we were able to confirm the diagnosis of cancer in the pancreas.

**SUBSCRIPTION TERMS** \$6.00 per year in advance, postage paid for the United States (medical students, \$3.50 per year); Canada, \$7.04 per year; Boston Union, \$8.52 per year for all foreign countries belonging to the Postal Union.

**MATERIAL** for early publication should be received not later than noon on Friday.

**THE JOURNAL** does not hold itself responsible for statements made by any contributor.

**COMMUNICATIONS** should be addressed to the *New England Journal of Medicine*, 8 Fenway, Boston, Massachusetts.

## MEDICAL OFFICERS' RECRUITING BOARD

The office of the Medical Officers' Recruiting Board of Massachusetts is located at 319 Longwood Avenue, Boston (telephone, ASP 3638); all physicians who desire commissions as medical officers in the Army of the United States should immediately communicate with the officers in charge.

## ANNUAL MEETING

THE one hundred and sixty-first annual meeting of the Massachusetts Medical Society, held May 25, 26 and 27 at the Hotel Statler, Boston, resulted in the largest registration of members, 1556, in the history of the Society, in spite of the fact that several hundred of those who, in the past, have

regularly attended these meetings are now away from Massachusetts, serving as medical officers in the United States Army and Navy. The luncheon meetings of the sections were well attended, but there was a distinct drop in the registration of wives, undoubtedly owing to the limitations to the program arranged by the Ladies' Committee that were necessitated by lack of transportation facilities. Never before have there been so many scientific and technical exhibits; the Ballroom and Ballroom Assembly of the Hotel Statler, however, are so well adapted for exhibits of this sort that both the members and the exhibitors were more than pleased with the arrangement.

The new schedule calling for the annual meetings of the supervising censors and of the Council during the late afternoon and evening of the day preceding the opening of the general sessions worked out very satisfactorily. The main items of business at the meeting of the Council comprised reports of the standing and special committees and the appointment of new committees. The following officers were elected for the year 1942-1943: president-elect, Roger I. Lee, of Boston; vice-president, Peirce H. Leavitt, of Brockton; secretary, Michael A. Tighe, of Lowell; treasurer, Charles S. Butler, of Boston; and orator, Edward P. Bagg, of Holyoke. Some controversy arose concerning the procedure to be adopted regarding graduates of approved medical schools who are in or about to enter the United States Army or Navy and who desire to become members of the Society; the matter was referred to the recessed meeting of the Council on the following day, and at that time, the Society, at its annual meeting, having voted to waive, for the duration of the present emergency, the by-laws relating to the timetable governing applications for membership from such graduates, two physicians whose applications were irregular were admitted to membership. At the same recessed meeting, Dr. Eliot Hubbard, Jr., of Cambridge, was elected assistant treasurer.

The annual meeting of the Society was unusually long, chiefly owing to considerable discussion concerning the proposed by-laws. Several members

opposed two of the regulations—that requiring five-year licensure in the United States before a graduate of a foreign medical school can apply for membership in the Society and that specifying that the Committee on Nominations shall cause its report to be published in the notice of the annual meeting of the Council; however, both these sections were passed by a vote of hands, and all the others by practically unanimous consent. At the close of the business meeting the incoming president, Dr. George Leonard Schadt, of Springfield, was introduced. Following the meeting, Dr. William B. Castle, of Boston, delivered the annual oration, “Some Remarks on Therapy for Anemia,” which appears elsewhere in this issue of the *Journal*.

Dr. Frank H. Lahey, of Boston, president of the American Medical Association, and Dr. Morris Fishbein, of Chicago, editor of the *Journal of the American Medical Association*, were the speakers at the annual banquet, which was attended by over 500 members and guests. Both emphasized the great need for young physicians in the armed forces, urged all under forty-five years of age to volunteer and warned that conscription will inevitably follow if the voluntarily enlisting personnel proves insufficient. The banquet was followed by the Shattuck Lecture, “Medicine and Air Supremacy.”\* The speaker, Dr. John F. Fulton, of New Haven, Connecticut, stressed the role that medicine has played in the development of combat aviation, particularly regarding the problems brought about by high-altitude flying, crashes and the care of pilots after injury; he predicted that within a year nearly twenty thousand flight surgeons and aviation medical officers will be needed in the Army Air Forces.

The majority of the papers read at the general sessions concerned one or another aspect of medicine as applied to the present emergency. Various problems of civilian defense were discussed, and mumps, tropical diseases, venereal diseases, skin diseases, head injuries, industrial health and mass immunization were considered in relation to the war effort. Other speakers commented on the effects of the war on public-health problems, medi-

cal education and American medicine in general, and the program was concluded by a symposium covering minor psychiatric disturbances in war and in civilian life.

All in all, the meeting was eminently successful, and one that will be remembered for many years by those who attended.

## THE COMMONWEALTH FUND

IN its twenty-third annual report, the Commonwealth Fund gives an account of its current effort to “do something for the welfare of mankind,” in accordance with the wish of its founder, Mrs. Stephen V. Harkness. A total of \$1,841,332 was appropriated for philanthropic purposes during the past year.

The policy of the fund paralleled that of previous years, in spite of adjustments made necessary by the war. Although the British fellowships offered since 1925 were suspended, although many members of nursing and medical staffs aided by the fund were called to military duty, and although a research project that had made great contributions to the knowledge of kidney function was halted because key workers went into national service, most of the undertakings progressed toward the goal of health maintenance and scientific advance. Subsidies and consultant services were furnished in twenty-eight states to encourage research and high standards of teaching in medical schools, to enrich and extend rural health services, to provide or improve hospital facilities in rural districts, and to furnish and reinforce community opportunities for mental-health services. The fund subsidized departments of preventive medicine at five medical schools and a department of psychiatry at another. A grant was made to the Peter Bent Brigham Hospital in Boston for the enlargement of its psychiatric service.

Since the war began, the fund has contributed \$685,000 for war relief and related activities. An epidemiologic unit, maintained by the fund in co-operation with Harvard University and the American Red Cross, is operating a hospital and field service for the control of communicable disease in England. And, through the British War Re-

of Society, support of the American Hospital in Britain has been maintained. The mental health services for children, provided through the Child Welfare Council, have proved their worth in the care and adjustment of the helpless victims of wholesale bombings.

Thus, in spite of curtailments demanded by the exigencies of wartime, the Commonwealth Fund continues its aid of scientific advance and its measures to relieve misery. Its zealous and humane efforts are an inspiration in a world in which the ideals of mercy and disinterest are challenged and must be fought for. The directors of the fund may well be proud of what has been achieved. Those who fight and those 'who only stand and stare' may be content that the torch of progress is in such hands.

## MEDICAL EPONYM

### PASTEUR TREATMENT

Louis Pasteur (1822-1895) reported his *Méthode pour prévenir la rage après morsure* [Method of preventing Rabies after Bites]" at the meeting of l'Académie des Sciences on October 26, 1885: a memorable account of its first application appears in the *Comptes rendus hebdomadaires des séances de l'Académie des sciences* (101:765-772, 1885). A portion of the translation follows:

After innumerable experiments, I have arrived at a prophylactic method that is practical and rapid whose success in dogs has already been frequent and certain enough to make me confident of its general applicability to all animals and to man himself. This method is based essentially on the following facts:

Inoculation of a rabbit by trepanation under the dura mater with rabid spinal marrow from a mad dog always transmits rabies to the animal after an average incubation period of about fifteen days.

If virus from the first rabbit is transferred by this method to a second, from this to a third and so on, there will soon be apparent a progressively increasing tendency to a diminution of the incubation period for bites in the successively inoculated rabbits.

The spinal cords of these animals are rabid through their extent, with a constant virulence.

If pieces a few centimeters in length are taken from these cords with all possible precaution regarding cleanliness, and if these are suspended in dry air, their virulence slowly disappears completely.

These facts being established, let us consider the method of rendering a dog immune to rabies, in a relatively short time.

A piece of fresh rabid cord from a rabbit killed by rabies, developed after seven days incubation, is suspended daily in one of a series of flasks, the air in which is kept dry by pieces of potash placed at the bottom of the flask. Each day, moreover, a Pravaz syringe full of sterilized bouillon, into which has been incorporated a small piece of one of these dried cords, is injected under the skin of the dog beginning with a small dose of which is a sufficient number of days

before the dry when the operation is performed so that one may be sure the cord is not virulent. On subsequent days, more recent spinal cord is used, separated by intervals of two days, until at last a very virulent cord is reached, which has been in the flask only a day or two.

The dog is now immune to rabies. He may be inoculated with rabid virus under the skin or even on the surface of the brain by trepanation, without the development of rabies.

By the application of this method, I had succeeded in obtaining 50 dogs of all ages and breeds that were immune to rabies, without having met with a single failure, when these presented themselves unexpectedly in my laboratory, on Monday, July 6 last, three persons from Alsace: Theodore Vone, a grocer of Meisengott near Schlestadt, who had been bitten in the arm on July 4 by his own dog, which had gone mad, Joseph Meister, aged nine years, also bitten on July 4, at 8 o'clock in the morning by the same dog. This child had been thrown to the ground by the dog and showed a number of bites on his hand, legs and thighs, several quite deep, that made it difficult for him even to walk.

The third person, who had not been bitten, was the mother of little Joseph Meister. Mr Vone had severe bruises on his arms, but he assured me that his shirt had not been pierced by the fangs of the dog. Since he had nothing to fear, I told him he might return to Alsace the same day, which he did. Little Meister and his mother I kept with me, however.

The death of this child seeming inevitable, I decided, not without keen and tormenting doubts as may well be supposed, to try on Joseph Meister the method that had always succeeded in my hands with dogs.

Therefore on July 6, at 8 o'clock in the evening, sixty hours after the bites on July 4, in the presence of Drs Vulprian and Grancher, the lad Meister was inoculated beneath a fold of the skin in the right hypochondrium, with a half Pravaz syringe of bouillon containing spinal cord from a rabbit dead of rabies on June 21, which had been kept since that time—that is, for 15 days—in a flask of dry air.

On subsequent days further inoculations were made, always in the hypochondria, as shown in the following table:

July 7, 9 a m	Cord of June 23 (14 day cord)
July 7, 6 p m	Cord of June 25 (12 day cord)
July 8, 9 a m	Cord of June 27 (11-day cord)
July 8, 6 p m	Cord of June 29 (9 day cord)
July 9, 11 a m	Cord of July 1 (8-day cord)
July 10, 11 a m	Cord of July 3 (7 day cord)
July 11, 11 a m	Cord of July 5 (6-day cord)
July 12 11 a m	Cord of July 7 (5 day cord)
July 13, 11 a m	Cord of July 9 (4-day cord)
July 14, 11 a m	Cord of July 11 (3-day cord)
July 15, 11 a m	Cord of July 13 (2-day cord)
July 16 11 a m	Cord of July 15 (1-day cord)

Nine rabbits were inoculated by trepanation with the various cords used so that the state of virulence of these cords might be followed.

During the last days, I had thus inoculated Joseph Meister with the most virulent rabid virus.

He had escaped, not only the rabies that his bites would have caused to develop, but that with which I had inoculated him as a control of the immunity conferred by that treatment—a rabies more virulent than that of the mad dog. From the middle of August, I viewed with confidence the future health of Joseph Meister. Today three months and three weeks after the accident his health remains all that could be wished.

## CASE HISTORY: FATAL MYELOGENOUS LEUKEMIA IN PREGNANCY

A twenty-eight-year-old married woman, whose past history was very incomplete, was transferred immediately to the hospital by the physician who saw her when she was six and a half months pregnant. On admission she was practically moribund. There was no history of prenatal care, but the patient had had anemia for some years. During the week before entry into the hospital, there had been increasing weakness, with multiple subcutaneous hemorrhages. Examination revealed marked pallor, a rapid, weak pulse, low blood pressure and a uterus just above the umbilicus. The urine was normal. Examination of the blood showed characteristic signs of myelogenous leukemia. There was no statement in the record about the size of the spleen. The patient, who was not in labor, died undelivered a few hours after entry. No autopsy was performed.

*Comment.* Myelogenous leukemia in itself is a rare disease, and its association with pregnancy is, of course, extremely rare. The general dictum of such a complication would obviously be to interrupt the pregnancy, because pregnancy would only aggravate the disease. That interruption would do anything except prolong life is undeniable.

Patients suffering from such blood diseases as myelogenous leukemia and pernicious anemia ordinarily do not become pregnant. Certainly, they should be advised against pregnancy.

## DEATHS

DOW — DAVID C. Dow, M.D., of Cambridge, died May 27. He was in his sixty-eighth year.

Born in Cambridge, Dr. Dow received his degree from Tufts College Medical School in 1898. He was an intern at Cambridge Hospital, where he was a member of the staff until his retirement a year ago. He was medical examiner of the first district of Middlesex County, and was a member of the Massachusetts Medical Society and the American Medical Association.

His widow, a son and a daughter survive him.

NEFF — IRWIN H. NEFF, M.D., of Detroit, died recently. He was in his seventy-fourth year.

Dr. Neff received his degree from University of Maryland School of Medicine and College of Physicians and Surgeons in 1889. He was a former superintendent of the Foxboro and Norfolk State hospitals, and was a former member of the Massachusetts Medical Society.

## WAR ACTIVITIES

## UNITED STATES ARMY

Base Hospital No. 6, recruited from the staff of the Massachusetts General Hospital, was recently ordered to active duty. The officer personnel is as follows:

*Commanding Officer:* Colonel Thomas R. Goethals.

*Surgical Service:* Lieutenant Colonel Horatio Rogers, chief.

*Medical Service:* Lieutenant Colonel Donald S. King, chief.

*Majors:* William T. S. Thorndike (registrar), Marshall K. Bartlett, Edward F. Bland, Henry H. Faxon, Trygve Gundersen, James A. Halsted, Sylvester B. Kelley, Alfred Kranes, Langdon Parsons, Robert G. Rae, Charles L. Short, Grantley W. Taylor, Jackson M. Thomas, Edward G. Thorp, John H. Talbott, James R. Lingley (chief, X-Ray Service) and James H. Townsend (chief, Section of Communicable Diseases).

*Captains:* Otto E. Aufranc, Francis H. Chaffee, Richard J. Clark, Lowrey F. Davenport, Daniel C. Dawes, Joseph H. Demers, John R. Frazee, John R. Graham, Thomas S. Hamilton, Henry M. Heyl, Daniel J. Holland, Theodore H. Ingalls, Alfred O. Ludwig, Otto D. Sahler, Spiros P. Sarris, Hermann B. F. Seyfarth, Oscar S. Staples, Somers H. Sturgis, Howard I. Suby, Eugene R. Sullivan, Garrett L. Sullivan, Howard Ulfelder, Claude E. Welch, Richard G. Whiting and John W. Zeller.

*First Lieutenants:* William E. Arnold, Robert M. Bailey, Edwin L. Canton, Calvin R. Coggins, Daniel S. Ellis, Marlow B. Harrison, Knowles B. Lawrence, Claude E. McGahey, John B. McKittrick, Sedgwick Mead, Frederick K. Poulin, Stanley W. Wyman, and William C. Burrage.

## CORRESPONDENCE

## PELLAGRA NOT A REPORTABLE DISEASE

*To the Editor:* At a meeting of the Department of Public Health on May 12, 1942, it was voted to remove pellagra from the list of reportable diseases. This action was taken because the disease has a very low prevalence in Massachusetts and the information which was being received from the reports was serving no useful purpose.

PAUL J. JAKMAUH, M.D.  
*Commissioner of Public Health*

State House  
Boston

## REPORTS OF MEETINGS

## BOSTON ORTHOPEDIC CLUB

A regular meeting of the Boston Orthopedic Club was held at the Boston Medical Library on January 19, with Dr. Otto J. Hermann presiding. The subject of the evening was "The Medical and Surgical Aspects of Gout."

The medical aspect was discussed by Dr. John Talbott, of the Massachusetts General Hospital. This disease is infrequent but not rare, and is usually undiagnosed for the first few years of its existence because its characteristic manifestations appear only in the later stages. This is in spite of the fact that the diagnosis is easily confirmed.

Gout may occur at any age from six to over seventy. There is periodic pain in multiple joints, with asymptomatic periods between attacks. At first, there are no residual manifestations, but later the interarticular changes brought about by the deposition of sodium urate appear. Although the resulting disabling symptoms may occur early in the disease, they never occur at the first attack. Any joint may be the site of attack, and the appearance of the joint in the acute stage closely resembles that in acute rheumatic fever or infection. A spread of the process may simulate cellulitis, but the skin is usually tense and cyanotic rather than red. Pitting edema and desquamation are occasionally encountered. There may be elementary or genitourinary prodromes, and an attack may occur while a patient is on accepted treatment. Sometimes a high-purine meal, recent surgery, an alcoholic bout, acute infection or trauma is the only initiating factor of an attack, and the interval between such an event and the onset may vary from a few hours to days. Each bout may last days to weeks, but there is usually a prompt response to colchicine. The interval between episodes may be as long as a decade at first, but subsequent attacks become more frequent. The association of bouts of pain with changes in weather is a real one. This has been explained by the finding that these patients have a diuresis shortly before the onset of joint symptoms, with a paradoxical gain of weight. When the barometric pressure is falling before a storm, a decrease in the insensible loss of fluid from the skin accounts for this apparent discrepancy.

The diagnosis of advanced tophaceous gout, with its tophi, increased blood uric acid content and punched-out areas of bone roentgenologically, is easily made. But it is essential to discover the early cases and thus possibly prevent some of the later sequelae by appropriate therapy. A presumptive diagnosis should be made on the history of repeated attacks of polyarthritis with no interval manifestations, a family history of gout, the excretion of urate crystals and a favorable response to colchicine therapy. The finding of a constantly elevated serum uric acid content is confirmatory evidence. The differential diagnosis involves practically all joint diseases, and any chalky secretions should be examined microscopically. For the determination of the uric acid levels, serum or plasma is preferable to whole blood, for the results are higher and the difference between normal and pathologic levels more definite. By this method, most normal patients have values below 5 mg. per 100 cc., whereas gouty patients are invariably above 6 mg. In 100 cases of gout in which 900 uric acid determinations were carried out at all stages of activity and quiescence in the past eight years, the level was over 6 mg. per 100 cc. in 99 per cent, with a variation from 5.7 to 16.0 and an average of 8.8. In 400 control determinations, the uric acid values were less than 6 mg. per 100 cc. in over 96 per cent, with an average of 4.1. Other conditions that may have a high value are renal insufficiency and leukemia. It is well known that many gouty patients have the former, and it should not be forgotten that leukemic patients may have other forms of arthritis. X-ray study is probably the least helpful in diagnosis, for the lesions are characteristic neither in place nor in kind. This aid should merely be used in suspected cases but not to rule the disease in or out of itself.

There is no known cure for gout, and residuums persist unless surgically removed. An asymptomatic period should not be accepted as a cure, but the condition may be fairly well controlled in most cases by the judicious use of appropriate therapy. The acute attack may be relieved by bed rest, high-fluid intake, soft-solid diet, a cradle over the part, sedation and colchicine. The drug

is best employed in the crystalline form in doses of 1/120 gr. every hour or two for eight to twelve times. Adequacy of dosage may be judged in the novice by the onset of nausea, vomiting and diarrhea, but the veterans know their capacity fairly well and can usually avoid these toxic manifestations. Improvement is evident in twenty-four to forty-eight hours, and repetition of a course of therapy should never be undertaken in less than two or three days. Otherwise, there will be toxic symptoms with a few doses and no relief of the gouty pains. There are no untoward reactions, sensitivities or the development of tolerance.

Treatment between attacks is almost impossible to evaluate because of the lack of a yardstick. Although the use of a low-protein and low-purine diet seems theoretically sound, its practical value is apparently exaggerated. Alcohol is not forbidden these patients despite its alleged role as an inciting factor. Cinchophen and its derivatives are banned because of the danger of liver damage and because it is not considered indispensable where colchicine is available. The use of mercury diuretics to cause an outpouring of fluid and urates was compared with a simple adenectomy in a case of lymphoma. Colchicine may be administered from every sixth day to every day, depending on the number of attacks each year, and this serves to keep the patient aware of both the disease and the drug; intensive therapy can thus be begun early in the prodromal stage. A high-fluid intake, as well as a reducing diet in obese patients, seems desirable, to relieve strain on affected joints. A high-vitamin and high-mineral diet is recommended, but no specific factor can be suggested as prophylactic.

Before discussing the surgical aspects of this disease, Dr. Robert Linton reviewed the history of gout in its relation to surgery. His cases were all in the late stages, and the procedures were often unorthodox from an orthopedic standpoint. The results were of course local and had no effect on the disease as a whole. The reasons for operation were pain, deformity and intractable ulcers. Before 1935, there were only seven operations at the Massachusetts General Hospital for the tophaceous deposits of gout, whereas between 1935 and 1941 Dr. Linton performed ninety-three operations on 11 patients. Formerly, the acute gouty joint was considered similar to that of an acute inflammation, and this was one factor in deciding against surgery. Another point, which has since been disproved, was the alleged lack of an adequate blood supply in gouty lesions. Dr. Linton has also found a decrease in the expected number of recurrences instead of the opposite. Eight patients were over fifty years of age, and 7 had had gout for over twenty years. The site of the operations—an indication of the relative prevalence of the condition—was as often in the hands as in the feet. The commonest type of growth was that involving the tissues down to but not including the bones and joints. Surprisingly, a third of the operations involved only the subcutaneous tissues and bursas. The notorious great toe was involved in only 5 per cent of all operations. The results in general were good, so far as relief of pain, decrease of deformity and increase of the function of the part were concerned. Healing was remarkably good, since sepsis occurred in only 3 per cent of cases, which were often ulcerated from the beginning. Several open lesions healed by primary union. It is necessary to institute measures to prevent the onset of acute attacks two to five days postoperatively, and colchicine in the usual doses three or more times a day for three days is sufficient. One important point of surgical technique is the use of transverse rather than longitudinal or elliptical incisions, even if multiple incisions then become necessary.

The discussion was opened by Dr. S. J. Thannhauser, of the Boston Dispensary. He stated that the polyarticular form of gout is much commoner in this country than in Europe. Italians predominate here, yet they do not have gout in Italy. They may learn new eating or other habits in this country that are conducive to the development of the condition. The difference between gout and the gouty attack was stressed by the speaker. The former is a metabolic disease in which the serum uric acid content is elevated. The latter, on the other hand, is not so clear, and may be dependent on some vasomotor instability. There may be some conditioning factor that explains why certain members of gouty families have attacks whereas others with equally high uric acid concentrations have none. Colchicine is good for the acute episode and should be so, for it has been shown that it exerts its effect on the vascular system. It has no effect on the gout or the uric acid content, although it does diminish the pain. Cinchophen, on the other hand, seems to be better for the gouty constitution and is not too dangerous.

In conclusion, Dr. Talbott stated that in his series the onset of an attack following a particular wine or meat was the exception rather than the rule. In patients studied on a metabolic ward over a period of months, no evidence of any effect of the dietary regimen could be noted. But this should not be construed to mean that patients who have such idiosyncrasies should not stay on a diet. Cinchophen has been found to lower the uric acid levels only intermittently, and nothing has yet been found to lower the values constantly and permanently.

NEW ENGLAND SOCIETY  
OF PHYSICAL MEDICINE

A meeting of the New England Society of Physical Medicine was held in the Bigelow Amphitheater of the Massachusetts General Hospital on January 21.

Dr. T. Stewart Hamilton, assistant director of the hospital, reported on one year's experience in the Physical Therapy Department. A rapid expansion in the use of the department was noted: there was an 87 per cent increase in the number of patients during the first six months. During one year, a total of 2100 patients received 21,266 treatments. The majority (56 per cent) of patients were referred by the Orthopedic Service. The percentages from the other departments were as follows: Medical, 12; Neurological, 10; Skin, 9; Fracture, 6; Surgical, 5; Eye and Ear Infirmary, 1.4; and Psychiatric, 0.6. Attention was called to a lack of understanding by many of the house officers, medical students and staff physicians of the principles of physical therapy and the value derived from its use in many conditions. An educational program has been started to remedy this. At present, a great deal of time and effort is being directed toward emergency training of physical-therapy technicians so urgently needed by army hospitals.

The practice of physical therapy at the Massachusetts General Hospital, as employed in the treatment of some familiar conditions, was described by Dr. A. L. Watkins, director of the Physical Therapy Department. A case of rheumatoid arthritis was presented to illustrate the deformities that may occur when attention is not given to proper orthopedic care and physical therapeutic measures. Prior to entry, this patient developed severe hip and knee flexion contractures and scoliosis in a marked degree. The patient was given bed rest, an adequate diet, and salicylates for control of pain, and the deformities were corrected by balanced leg traction on a Bradford frame. The muscles were strengthened, and the function of joints

was regained by supervised therapeutic exercises, at first under water in the Hubbard tub, and later by gait instruction in the walker. Attention was given to postural exercises to improve body mechanics. Local heat to joints in the form of radiant heat lamps, paraffin baths, hot wet packs and diathermy was found helpful in controlling pain, and allowed greater function of involved muscles and joints.

Cases of Bell's facial-nerve paralysis, with early and late recovery, were presented. Patients who did not show a reaction of degeneration usually recovered within three to six weeks regardless of the treatment, whereas with complete nerve degeneration, several months elapsed before beginning function was noted. In these cases, abnormal contractions of all facial muscles occurred, which is described as mass action. This phenomenon was demonstrated by electromyographic recordings. The treatment consisted of splinting, radiant heat, gentle massage, electrical muscle stimulation and graded active symmetrical exercises when possible.

In peripheral-nerve injuries, a test for quantitating the electrical excitability of degenerating and regenerating nerves by means of stimulation by measured condenser discharges was found to be of value in detecting recovery at an early date.

Copper sulfate iontophoresis was used in the treatment of facial pitting and scarring from chronic acne vulgaris, with gratifying results.

The technic of histamine iontophoresis was demonstrated. This measure was useful in producing prolonged local hyperemia for symptomatic relief of muscle pain and spasm in those conditions commonly called "periarticular rheumatism" and "fibromyositis."

Conventional long-wave diathermy has been found to be the treatment of choice in addition to immobilization for nonpurulent sclerosing tenosynovitis. When the acute inflammation has subsided, the whirlpool bath and graded active exercises are started.

The treatment of a compound fracture of the elbow, with radial-nerve involvement, was discussed. This consisted in radiant heat and gentle stroking massage, without elbow motion at first. When bony union permitted, whirlpool bath and guided active exercises of graded intensity were added. The radial-nerve paralysis was followed with electrical and functional tests, which showed spontaneous regeneration. At the end of six months, elbow motion was 80 per cent of normal, with good regeneration of the radial nerve. The patient then started work on the hand loom in the Occupational Therapy Department, to gain further supination and muscle strength and to prepare him psychologically for an early return to work.

An analysis of the types of treatments given during the past year (Table 1) revealed that simpler measures, which

TABLE 1. Analysis of Cases Treated during 1940.

TYPE OF TREATMENT	NO OF TREATMENTS	PERCENTAGE OF TOTAL
Radiant heat	9262	22.2
Massage	8661	20.9
Therapeutic exercise	16318	39.3
Hydrotherapy	2680	6.6
Ultraviolet light	1739	4.2
Diathermy	1918	4.6
Electrical stimulation and iontophoresis	926	2.2

are also suitable for home use, constituted approximately 90 per cent of the treatments. More elaborate measures involving electrotherapy constituted the remaining 10 per cent.

the new Physical Therapy and Occupational Therapy treatments were opened for inspection at the end of the month

## BOOK REVIEWS

*Eye Lining* By C E Turner, A M, Sc D, Dr P H, Elizabeth McFloss, B S, M A 8°, cloth, 432 pp., with illustrations St. Louis The C V Mosby Company, 1941 \$1.90

A textbook for the instruction of school and college students in the fundamentals of healthful living, this work based on actual classroom experience, and the material well organized and adequately presented

*Mayo Clinics A Mayo Clinic monograph* By Fred A Willis, M.D., MS in Med 8°, cloth, 276 pp., with 35 illustrations St. Louis The C V Mosby Company, 1941 \$4.00

Since there have long been the most popular form of post graduate education in American medicine because the average physician is more interested in finding out what is being practiced than what is being preached. It is through such teaching clinics that many bits of empirical clinical lore are passed along — information that, perhaps, not been dignified by inclusion in the textbooks. Dr Willis' volume has been compiled from actual discussions, which have previously appeared in the *Staff Meetings of the Mayo Clinic*. It is perhaps the first book of this type devoted exclusively to heart disease, and it makes for good reading. Examples of all the common etiologic factors of heart disease, as well as a number of unusual cases are included

*Cancer of the Face and Mouth. Diagnosis treatment and repair* By Vilray P Blair, M.D., Sherwood Moore, M.D., and Louis T Byars, M.D. 4°, cloth, 599 pp. with illustrations and 64 plates St. Louis The C V Mosby Company, 1941 \$10.00

This book is designed to help the practitioner who first meets the patient with cancer of the face and mouth. It emphasizes the need for early recognition of cancer, but places main stress on the handling of the delayed or recurrent case. Many of the patients presented might be considered incurable, but the results show that even in advanced cases one can achieve brilliant cures by the institution of proper therapy

The method of destroying cancer about the face and oral mucosa varies in different clinics. Dr Blair and his associates frequently use electrosurgical and cautery destruction. A slough is thus formed that clears away and leaves a clean base of granulation tissue. This method has the further advantage of allowing time for the detection of recurrence and its elimination before a plastic procedure is undertaken. In cancers of the tongue, local institution of radium has been used to the exclusion of surgery in the last ten years. In some cases, surgery was delayed at a later date to remove a thickening in the scar or by recurrence

Some will differ with the authors in their selection of treatment for individual cases. Apropos of this is the statement from the text, "It is not so much lack of treatment as poor selection of the kind of treatment that has most often disappointed the average recurrent case that we encounter today, but lack of conviction, temporizing methods and hurried execution. It is not delayed treatment but hasty treatment that seems to lessen the quality of our therapeutic results"

The last part of the work is devoted to a discussion of the various procedures, half the space being taken

up by the steps involved. These illustrate the cases discussed in the previous text. By this method, one is kept constantly in touch with the actual case. There is an excellent discussion of neck dissection and radiation therapy in the management of each type of lesion

Dr Blair and his group have presented a most difficult problem in a manner that will give immeasurable help to the many surgeons and practitioners throughout the country who treat patients with cancer of the face and mouth

*Wounds and Fractures A clinical guide to civil and military practice* By H Winnett Orr, M.D. 4°, cloth, 227 pp. Springfield, Illinois Charles C Thomas, 1941 \$5.00

The timing of this publication was perfect — dramatically so. In the hands of the author, the results obtained by following the technic outlined may be all that he claims. For situations in which there is such a press of work to be done that timesaving and lack of trained attendants are vital factors it is conceivable that the method may have advantages. One gets the impression that the author believes that he has introduced something new into the practice of surgery besides infrequent dressings, when he cites adequate fixation, correction of deformities, overcoming shortening and prevention of, and protection from, infection as the fundamental objects of fracture treatment

His advice to ignore the existence of shock in determining the time to institute the surgical measures needful to fulfill the above mentioned cardinal principles of fracture treatment and the assertion that a little infection in the vicinity of the fracture site may be helpful, on the ground that it might stimulate callus formation provided the wound is well drained are at least debatable. No well trained surgeon closes a wound when he has any doubt of its freedom from infection, nor does he dress it more frequently than need be. Plaster-of-Paris fixation, in skillful hands undoubtedly provides the best security for the fragments. A minimal use of hardware to secure and hold fractures in proper alignment is at times desirable, but to insert a pin indiscriminately in every case, unless it is clear that no other method will suffice, is failing to exercise good judgment, at least in the opinion of the reviewer

The chapters on the treatment of nerve injuries as a complication of fracture management and on the value of physical therapy are adequate.

The appended bibliography is confined to a list of the author's own writings on the subject of fractures

*X Ray Therapy of Chronic Arthritis* By Karl Goldhamer, M.D. With a foreword by Harold Swanberg, M.D. 8°, cloth, 131 pp., with 24 original illustrations by the author, 4 roentgenograms and 4 tables Quincy, Illinois Radiologic Review Publishing Company, 1941 \$2.00

This small monograph attempts to summarize current knowledge concerning chronic arthritis and experience with its treatment by x rays. The author, a man of wide roentgenologic experience, has presented with commendable frankness his data in the treatment of 100 patients suffering from chronic arthritis. The drawings of the roentgenologic findings are good but do not show the changes so well as good photographs of x ray films

The author believes that x ray therapy acts on chronic arthritis by stimulating hyperemia and producing improved nutrition in the joint, and also that it produces an analgesic of varying duration. He claims that better results can be expected in the early case than when the arthritis has been present a long time. The techniques are described for the various types of arthritis. The reviewer

gained the impression that the author, like many other sponsors of measures of definite value, is somewhat over-enthusiastic.

*Endocrinology: The glands and their functions.* By R. G. Hoskins, Ph.D., M.D. 8°, cloth, 388 pp., with 14 illustrations. New York: W. W. Norton and Company, Incorporated, 1941. \$4.00.

It is always difficult to write a book on a scientific subject that will be of value both to the general reader and to the student of the subject. Essentially, this is what the author has undertaken, this work being based on an earlier book, *The Tides of Life*, which appeared in 1933. As Dr. Hoskins states in the preface, "The material has been brought up to date and amplified with an eye particularly to the needs of biologists, psychologists, premedical students and those physicians who desire a not-too-technical introduction to the science of the hormones. I have also tried, however, to keep for the most part within the comprehension of the intelligent general reader." The reviewer believes that there are few general readers with sufficient biologic and medical knowledge to follow the author's discussion with much understanding. For the other group mentioned, it should be very useful.

The author has dedicated the book to "W. B. C." (Walter B. Cannon). After a brief introduction on hormones as chemical regulators, a chapter is devoted to each endocrine gland. There is a chapter on general aspects of endocrinology, such as its relations to the nervous system, the interrelations among the endocrine glands, racial characteristics, endocrine diagnosis and therapy, and endocrine factors in personality. Finally, a short discussion of "Endocrinology of the Future" enumerates some of the unsolved problems of the present that it is hoped will eventually be solved.

The material has been well chosen and clearly presented. Some few statements seem open to question. For example, on page 43, it is stated, "Despite its profound effects in adrenal deficiency, an excess of cortin apparently does no harm." Again, on page 329, the author implies that diabetes is generally treated with a high-fat, minimum carbohydrate diet. But on the whole, the book is most carefully written. There are references at the end of some of the chapters, and a brief general list of sources at the end of the book. A good index is included.

*Epilepsy and Cerebral Localization: A Study of the mechanism, treatment and prevention of epileptic seizures.* By Wilder Penfield, M.D., D.Sc. (Oxon., Princeton) and Theodore C. Erickson, M.Sc., M.D., with a chapter by Herbert H. Jasper and one by M. R. Harrower-Erickson. 4°, cloth, 623 pp., with 163 illustrations and 17 tables. Springfield, Illinois: Charles C Thomas, 1941. \$8.00.

A complete treatise on epilepsy, particularly one that would reflect the vast amount of research on this disease, has long been needed by the medical profession. In recent years, six general books have been published: one in French by Crouzon (1929), one in German by Frisch (1937) and four in English by Lennox and Cobb (1928), Muskehs (1928), Jackson (1931) and the extensive and able reports by many investigators issued by the Association for Research in Nervous and Mental Diseases (1931). All these books are at least ten years old, at a time when more knowledge of the treatment of epilepsy

has been added to medicine than in any other comparable decade.

It is of interest, moreover, that this book should have come from a neurosurgical clinic, the first to do so, which reflects the importance of surgery in the treatment of the convulsive state. Medical treatment is by no means neglected in this volume, but, as might be expected, the tone is set by surgery: experimental, investigative and therapeutic. Chapters are added on electroencephalography and on psychologic studies of epileptic patients.

The chief sections deal with the history of the disease, seizure patterns, — of which the senior author has been the leading investigator, — cerebral localization of these patterns, epileptogenic lesions, such as scars and tumors, the radical treatment of such lesions, diffuse diseases of the brain with cryptogenic epilepsy, and acute head injury. Clearly presented and carefully considered, the material is largely factual and reports, without too wide a generalization, what the authors have seen and reasoned about in their large clinic. This is therefore a personal book, a report of stewardship, largely by Dr. Penfield, who, in training and habit of thought, is eminently fitted to present his findings. That everyone will agree with the amount of surgical therapeutics he uses or with the value of some of his work as a practical form of relief is not to be expected. What is acceptable by the whole profession is a careful study of the epileptic constitution, in which Penfield and his colleagues have had a leading part.

For all who wish to be abreast of the times in the study and treatment of one of the most widespread and disabling of diseases, long an outcast from research, this fine product, in a fitting format, is recommended.

*An Introduction to Medical Science.* By William Boyd, M.D., M.R.C.P. (Edin.), F.R.C.P. (Lond.), F.R.S. (Canada). Second edition, thoroughly revised. 8°, cloth, 358 pp., with 124 illustrations. Philadelphia: Lea and Febiger, 1941. \$3.50.

Someone defined the introduction to a book as that part written last, printed first and seldom read. Although such a statement may be true of some books that are written to introduce the reader to a particular art or science, it is not so with this volume, which attempts briefly to encompass medical science and yet contains numerous facts accurately and delightfully recorded. In the second chapter, the author gives a bird's-eye view of the evolution of medical science. In eight pages, he covers the ground from the magic man or the witch man of primitive times to the magic bullets — chemotherapy — of the present day. As on an airplane trip, one visualizes the high peaks on the long journey. This is true of every chapter, and many facts are recorded in an authoritative and attractive manner. Dr. Boyd handles the microscope and the pen with equal dexterity. The following sentence is a striking example: "The gall-bladder has the same nerve supply as the stomach, so that the symptoms of gall-bladder disease are usually referred to the stomach, which seems to cry aloud in sympathy."

This is a book primarily written for nurses. Any nurse who can master all the facts presented will certainly serve in her profession more intelligently. The volume is highly recommended, for it is the product of a person who knows the facts and knows how to present them.

## CHEST PAIN IN PATIENTS WITH MITRAL STENOSIS, WITH PARTICULAR REFERENCE TO SO-CALLED "HYPERCYANOTIC ANGINA"\*

ALEXANDER M. BLUMFELD, JR., M.D.,† AND LAURENCE B. ELLIS, M.D.‡

BOSTON

PATIENTS with mitral stenosis often complain of chest pain. Pain also frequently occurs from causes unrelated to the heart, but such pain is not discussed in this paper. There are four main varieties of chest pain especially associated with mitral stenosis: that of cardiac neurosis, that of active rheumatic carditis; angina pectoris, and so-called "hypercyanotic angina." In none is the pain directly produced by the stenosed mitral valve. In addition, patients with mitral stenosis are prone to develop pulmonary infarction and may have repeated episodes. Pain may be present either as pleural pain of an associated pleuritis or as substernal distress, especially with massive pulmonary infarctions or emboli.

### PAIN OF CARDIAC NEUROSIS

Without doubt, the type of chest pain that patients with mitral stenosis most commonly complain of is that of cardiac neurosis, such pain, for which no organic cause can be demonstrated, is largely psychogenic in origin and usually dependent on an anxiety state. It is very variable, ranging from aching soreness or pins and needles sensation, to sharp, stabbing or lancinating, and is usually felt in the apical region, occasionally all over the precordium and even sometimes in the chest and down the arms. It has no constant relation to exertion and frequently persists for hours or days. The pain is often attended by precordial hyperesthesia. Breathlessness, which in reality consists in sighing or a sense of inability to get enough

air into the lungs, is a common complaint. There may or may not be associated manifestations of neurocirculatory asthenia such as tachycardia, palpitation, cyanotic cold extremities, fatigability and poor response to effort. Part of the usual diagnosis of such functional pain is the absence of evidence of organic heart disease, but not uncommonly patients with unquestionable organic heart disease, including mitral stenosis, have unmistakable functional pain. The association is obviously explained by natural anxiety when patients know of their heart disease and its dangers. Does marked enlargement of the heart, such as some patients with mitral stenosis have, in itself cause precordial pain? Certainly, patients with very large hearts beating forcibly against the chest wall are likelier to have heart consciousness than normal persons, but such a sensation rarely, if ever, reaches the degree of true pain in the absence of a neurotic or anxiety factor. The following is a typical example of a patient with the functional type of pain.

CASE 15. The patient a 42 year old woman, who had rheumatic fever in her youth, but following this led a normal life, was married and had two children. Following the birth of the second child, she did not regain her strength, but suffered from breathlessness at her accustomed tasks and complained of a great sense of fatigue and of sleeplessness and precordial pain. She was seen in consultation at this time by an able cardiologist, who found mitral stenosis and apparently interpreted this as the cause of her complaints and stressed merely the necessity of a cautious regime on her and her husband. For 20 years the patient was up only a few hours a day, rarely went out, and was almost constantly conscious of her heart. Distressing precordial pain was the most prominent of her many symptoms. She never developed congestive failure. Suddenly, after 20 years of cardiac neurosis and no heart failure, without warning, she developed a right hemiplegia, probably from an embolus. She recovered partially from the paralysis, but her personality clearly changed. She became cheerful, fearless and free from complaints. There

§Now in medicine, Harvard Medical School, assistant visiting physician, Boston City Hospital, assistant physician, Thorndike Memorial Laboratory.

††This case has previously been cited by Ellis and Blumfeld.

was no more mention of consciousness of the heart and heart pain. The patient struggled about the house doing more work than she had done at any time for the previous 20 years, and remained up all day. This state continued until she was lost sight of several years later.

The pain in this patient was of the severe type described above. For twenty years, she was disabled by a functional state, aggravated undoubtedly by the misinterpretation of symptoms by the cardiologist who first saw her. The spontaneous relief of the neurotic symptoms with the onset of an organic disability, the hemiplegia, is of interest and has been discussed elsewhere.<sup>1</sup>

#### PAIN OF ACTIVE RHEUMATIC CARDITIS

It is well known that pain in the chest may accompany active rheumatic carditis. This symptom has been thoroughly discussed by Swift and Hitchcock.<sup>2</sup> This type of pain is said to be commonest in acute recurrences of rheumatic fever, and accordingly should sometimes appear in patients with mitral stenosis. The following case illustrates most of the typical features of this type of pain.

CASE 2. A. M., a 37-year-old woman, had had acute rheumatic fever at the age of 14, and had been known to have mitral stenosis and auricular fibrillation for several years. She entered the Boston City Hospital because of persistent, dull, heavy, aching pain, located in the mid-sternal region and nonradiating. In association with this was hyperesthesia of the precordial region of sufficient degree to make cardiac percussion uncomfortable to the patient. She had, on admission, in addition to the physical signs of her valvular lesion, mild migratory joint pains, a slight fever, leukocytosis and elevated sedimentation rate. As these latter findings disappeared so did the patient's precordial pain and hyperesthesia, and she recovered uneventfully.

The pain in this case was consistent with cardiac neurosis, but there were no other neurotic symptoms, and the occurrence and subsidence of the pain in conjunction with the onset and disappearance of signs of rheumatic infection indicate its relation to active carditis. Active rheumatic carditis may be accompanied by pericarditis, and if the diaphragmatic or a certain part of the pleural pericardium is involved, there may be pain in the precordium, the root of the neck or upper abdomen.

#### ANGINA PECTORIS

It has long been recognized that angina pectoris is rarely associated with mitral stenosis. White<sup>3</sup> found mitral stenosis in but 2 of 500 cases of angina. Hamilton and Thomson<sup>4</sup> found but one patient with an unmistakable story of effort limited by angina pectoris among many hundred young women of child-bearing age with mitral stenosis. Although evidence exists that rheumatic fever may

produce or hasten organic disease of the coronary arteries,<sup>5</sup> the rarity of angina pectoris except in patients in the older age group and usually with other clinical evidence of arteriosclerosis makes it probable that when this symptom does occur it is usually due to a superimposed coronary atherosclerosis and does not differ essentially from angina pectoris occurring in patients without valvular heart disease. Blackford<sup>6</sup> has recently reported 2 cases of angina in patients with mitral stenosis who had normal coronary arteries. One of these cases presented features suggesting that it falls into the group of "hypercyanotic angina," discussed below. Uncommon as angina pectoris is in association with mitral stenosis, acute myocardial infarction is even rarer. White<sup>7</sup> did not encounter a single case of mitral stenosis in a series of 200 cases of myocardial infarction. The characteristics of the pain of angina pectoris are too well known to need description. The following is an example of a case of angina pectoris and mitral stenosis.

CASE 3. P. R., a 50-year-old man, entered the hospital in acute congestive failure and stated that for the previous 5 weeks he had had increasingly frequent attacks of severe precordial pain and tightness, precipitated by even mild exertion and radiating down the left arm in the form of "numbness" or a "twisting" pain. The patient had a clear history of several attacks of rheumatic fever in childhood and typical physical and x-ray findings of mitral stenosis. The patient's failure responded to the usual treatment, but when allowed up and about he had frequent return of his precordial pain on effort.

#### HYPERCYANOTIC ANGINA

Perhaps the most dramatic precordial pain occurring in patients with mitral stenosis is the unusual type of paroxysmal precordial or substernal pain, called "hypercyanotic angina" by some authors. This pain, since it occurs principally in cases of severe mitral stenosis, may well bear some direct relation to the valvular lesion. The pain is severe and may be excruciating, lasting hours or even days in extreme cases. It is clinically indistinguishable from the pain of an acute myocardial infarction but is associated with none of the electrocardiographic changes, fever and leukocytosis that accompany the latter, and at post-mortem examination there is no evidence of infarction. The following cases are presented as extreme examples of this type.

CASE 4. E. R., a 33-year-old woman, gave a history of rheumatic fever in young adult life, and signs of progressively diminished cardiac reserve for 6 years. For 2½ years, she had suffered increasingly frequent and severe attacks of dyspnea, orthopnea, cyanosis and very severe precordial pain, burning in character and radiating to the left side and back of the chest, with a sensation of warmth in the left arm. The first attack was of 5 days' duration and was repeated in varying degrees of severity during

the months prior to entry. Between attacks, the patient was quite well except for mild exertional dyspnea and the occurrence of five hemoptyses.

On entry, the patient seemed acutely ill, complaining of severe pain, with marked cyanosis, moderate orthopnea and some venous distention. There was slight congestion of the right lung base. The heart was enlarged, with signs of mitral stenosis, and the liver was enlarged and slightly tender. The blood pressure was 68/30, and rose to a normal level following the attack. The patient responded to oxygen and sedation, and the patient was then well except for low grade fever and leukocytosis. Attacks of pain recurred several times during the hospital stay, always with severe cyanosis, pulmonary edema and collapse, and oxygen seemed always to be the deciding factor in their relief. Electrocardiograms showed T-wave abnormalities affecting digitalis therapy, and they showed no change during the entire course except for a shift from sinus rhythm to auricular fibrillation. The patient died during the 12th hospital week in another severe attack of preterminal pain.

Post-mortem examination revealed a markedly stenosed, thickened and fixed "button-hole" mitral valve, a normal size of coronary arteries, which were patent and showed no sclerosis, and a myocardium that was hypertrophic in the region of the right ventricle but otherwise unremarkable. The pulmonary changes in this case were very marked and have been reported in detail by Parker and Cass<sup>8</sup> in their study of pulmonary vascular changes secondary to mitral stenosis. These changes consisted in general of marked capillary dilatation, with a tendency to aneurysmal bulging into the alveolar lumens; thickening of the capillary basement membrane, a tendency to intimal fibrosis in the alveolar walls and in many areas the appearance of a cuboidal type of epithelium in the lumen. The larger arterial vessels showed a proliferative arteritis.

Case 5. J. P., a 65-year-old woman who had had acute rheumatic fever in childhood, entered the hospital because of several weeks of intermittent severe "pressure-pain" in the left chest, with radiation to the left arm, which had been almost constant for the 2 weeks prior to admission. It was unrelated to activity. On entry, the patient showed orthopnea, cyanosis and extreme prostration. The heart was totally irregular, and there was a rough apical systolic murmur. There were slight pulmonary congestion and minimal peripheral edema. The blood pressure was 110/50. The patient continued to be apparently in extremis throughout the entire 1st hospital week, after which she improved slightly but had frequent recurrences of pain, and she was discharged after 4 months.

During the succeeding year, the patient entered three or four times for similar severe episodes, the last admission being 5 weeks of apparently continuous pain and prostration. At all these admissions, there was slight objective evidence of pulmonary congestion and none of peripheral edema. At the last entry, physical and electrocardiographic findings were still those of the first admission. The patient died on the 32nd hospital day following her severe attack.

Autopsy showed a 300 gm. heart, the coronary vessels having normal patency but mild atheroma, and the myocardium showed only microscopic perivascular fibrosis. The mitral valve was thickened and stenosed, and the coronary vessels showed changes similar to those in Case 4 although somewhat less marked.

Case 6. M. Y. entered the hospital six times between the ages of 48 and 58. She gave a history of two attacks

of acute rheumatic fever in early adult life, and for 18 months prior to entry she had had bouts of severe precordial pain radiating down the left arm and accompanied by cyanosis and dyspnea. On each entry, the story was striking, with severe and prolonged precordial pain and cyanosis—lasting several hours at a time and not related to exertion. There was evidence of slight persistent pulmonary congestion, but no peripheral edema, throughout each entry. Attacks recurred at frequent intervals, and were best relieved on those occasions when the patient received oxygen therapy in the hospital. During one attack, the blood pressure rose from 150/100 to 200/130, returning subsequently to its previous level; in another attack, the blood pressure fell. The patient had chronic auricular fibrillation throughout her course, and marked signs of mitral valvular disease. The final hospital admission followed a month of continuous pain and congestive heart failure and ended in death. The only electrocardiographic change from the findings at the first admission until death was a gradual shift of the axis toward the right. Unfortunately, permission for post-mortem examination was denied.

## DISCUSSION

In brief, the picture presented by the last 3 cases and by a few similar ones in the literature is as follows. The pain is severe, squeezing or grinding, located in the precordium or beneath the sternum, radiating to the left shoulder and arm, bearing no clear relation to exertion, emotion or stress, and occurring in paroxysms that may last for hours or days. In addition, there are usually dyspnea, orthopnea and a severe degree of cyanosis during the attacks, and in some cases marked circulatory collapse. Peripheral venous congestion may or may not be present. Although our patients all had some congestion of the lungs at the time of the attacks, the relation of the pain to heart failure is by no means constant. The picture that these patients present is often unlike the usual manifestations of heart failure. Their cyanosis may be extreme, and their dyspnea and orthopnea well marked at a time when the signs of pulmonary congestion are surprisingly few. Roentgenograms of the lung fields are likelier to show markedly increased hilar markings and shadows of enlarged pulmonary vessels fanning out from the hilum than the usual basal congestion.

There is not the fever, leukocytosis or electrocardiographic pattern of an acute myocardial infarction, and the changes in blood pressure are irregular and in no way characteristic. Oxygen relieves the pain much more effectively than vasodilator drugs. Post-mortem examination shows a high degree of mitral stenosis, with secondary myocardial hypertrophy and pulmonary vascular changes.

This symptom complex, which is by no means new, is seen occasionally in most large clinics. It is, however, confusing and often leads, as in all 3 of our cases, to a mistaken diagnosis of myocardial

infarction. Striking as it is, it has received relatively little attention in the medical literature and has escaped mention in most of the standard texts. It is probable that mild grades of this syndrome occurring in patients with marked mitral stenosis are not so uncommon as observers have thought.

The first definite mention of chest pain as a feature of mitral stenosis is contained in an article by Nothnagel,<sup>9</sup> who, in 1891, presented statistics concerning the frequency of occurrence of pain in all types of valvular heart disease. The aortic lesions, of course, led the field, but it is of interest that he recorded pain in 18 per cent of his cases of mitral stenosis. He further reported a case of severe prolonged precordial pain in a thirty-six-year-old woman whose story is very similar to that in Cases 4, 5 and 6.

Since the turn of the century, there have been a few scattered articles dealing with pain of this type, further describing and sometimes attempting to explain it. Vaquez and Giroux,<sup>10</sup> in 1908, described the clinical picture of *angina pulmonaire hypercyanotique*, which they considered a consequence of pulmonary vascular abnormalities. Posselt,<sup>11</sup> in the same year, mentioned *Dyspragia intermittens angiosclerotica pulmonalis*, apparently the same syndrome, as one of the criteria to be used for the clinical diagnosis of pulmonary arteriosclerosis, and suggested that the pain might be produced by distention of the pulmonary arteries caused by pulmonary arteriolar spasm. In 1911, Frugoni<sup>12</sup> contrasted the *dolor pallidus* of ordinary effort angina with the *dolor caeruleus* in patients with sclerosis of the pulmonary vascular system. He believed that the pain had a distinctive type of radiation, differing from that of ordinary angina, from the precordium deep into the chest, an opinion that was echoed by Engelen<sup>13</sup> in 1923. Arrillaga,<sup>14</sup> in discussing Ayerza's syndrome, comments on the occasional occurrence of pain of the type described by Posselt.

The writings of Brenner<sup>15</sup> on the pathology of the pulmonary circulation contain some further mention of hypercyanotic angina occurring in patients with secondary pulmonary arteriosclerosis. Of particular interest, however, is the case that he cited of an eleven-year-old boy who had primary pulmonary arteriosclerosis of sufficient degree to cause marked right ventricular hypertrophy. The description of the pain is identical with that in our cases. This is, interestingly enough, the only case of this phenomenon in the literature occurring in a male. Brenner suggests that the pain is the result of myocardial anoxia, which is caused by the severe anoxemia.

Brill and Krygier,<sup>16</sup> in a recent review of primary pulmonary vascular sclerosis, commented on the oc-

currence of chest pain in 4 of the 20 cases they assembled from the literature, including 1 reported by themselves, and considered that the pain was probably due to acute coronary insufficiency consequent to a diminished volume of blood delivered to the left ventricle through an obstructed pulmonary circulation.

In the foregoing discussion, attention has been devoted primarily to disorders of the pulmonary circulation. Although in some cases these disorders are associated with mitral stenosis, they frequently occur in patients suffering from chronic pulmonary disease or even primary pulmonary vascular disease.

There has been some comment in the literature specifically of the association of pain of this type and mitral stenosis. Parker and Weiss<sup>8</sup> mentioned pain and cyanosis prominently among the symptoms of their cases of mitral stenosis with severe secondary pulmonary changes, and commented on their absence in the control cases with a normal pulmonary circulation. They made the suggestion that the cyanosis is due to a number of factors. The alveolar capillaries are so dilated as to allow simultaneous passage of several columns of red cells instead of the normal one, with consequent inefficient oxygenation, and the structural changes that they describe are such as to increase greatly the thickness of the membrane through which the gaseous exchange must occur.

Some authors have attributed the pain to strictly intracardiac explanations of conditions. Sternberg,<sup>17</sup> in reporting the autopsy findings in a twenty-six-year-old woman with mitral stenosis who had severe precordial pain for five days preceding death, noted that the coronary arteries were unusually thin and collapsible, and suggested that the terminal precordial pain was the result of compression of the left coronary artery in its course between the left auricle and the pulmonary conus, which were distended as a consequence of the mitral stenosis. Hochrein<sup>18</sup> later took issue with this theory, stating that in his experience pain had been independent of the degree of decompensation. He offered an alternative explanation based on the post-mortem findings in 1 of 4 cases that he reported. Using a special technic, he demonstrated that the left coronary orifice was pulled down and distorted as a result of the contraction of a scarred mitral valve and its shortened chordae tendineae. This, he suggested, had sufficiently impaired the coronary flow to explain the pain.

It seems reasonable to assume, from the character and location of the pain, that it arises from anoxia of the myocardium. The relief of pain by oxygen that occurred in our patients certainly suggests that anoxia is the cause and that general de-

saturation of the blood with oxygen is an important factor. In addition, there is probably a decrease in the amount of blood reaching the left side of the heart through the impaired pulmonary vascular bed, and hence the left ventricular output is diminished. This in turn causes impairment of coronary blood flow, which thus further enhances the myocardial anoxia. It is likely that an abnormal heart is also a necessary part of the picture in addition to an abnormal pulmonary vascular system producing anoxemia and diminished blood flow. Although disease of the coronary arteries may be present, it is unnecessary in the production of the clinical syndrome, and, in view of the cases of primary and secondary pulmonary vascular disease cited above, mitral valvular disease is also not an essential feature. The common denominator of all cases is myocardial hypertrophy of the right ventricle.

The pain in character and duration is similar to that occasionally seen in patients with impaired coronary circulation or myocardial hypertrophy, or both, who develop coronary insufficiency as the result of paroxysmal tachycardia. In our cases, tachycardia of any degree did not occur.

In severe mitral disease, several factors could promote deficiency of the myocardial oxygen supply. In the first place, the increased load of work thrown on part of the myocardium by the damaged valve creates an abnormally high need for oxygen, and hypertrophy of the overworked portion of the myocardium, which in itself constitutes an unfavorable situation from the nutritional standpoint, makes this increased need the more difficult to meet. When one adds to this the anoxemia that is present, and an impaired coronary blood flow resulting from a cardiac output diminished by the obstruction in the pulmonary circulation, as well as the mechanical narrowing of the mitral orifice, the presence of pain is not surprising.

It is to be recognized that the foregoing explanation does not answer all the questions posed by this syndrome. One such question is the lack of definite correlation between the pain and exertion. One must assume that the capacity of these patients for physical exertion was sharply limited by dyspnea before pain occurred. When they became well compensated, oxygenation was sufficient to allow for moderate effort without pain. The lack of electrocardiographic change during the attacks is of interest, since it is well known that electrocardiographic abnormalities may develop during coronary insufficiency occurring in angina pectoris or from other causes. However, such alterations

in the electrocardiogram are by no means invariable in angina pectoris, and it is quite possible that further electrocardiographic studies on patients with hypercyanotic angina will reveal on occasion alterations consistent with coronary insufficiency. Furthermore, since the myocardial anoxia is general and not focal, striking electrocardiographic abnormalities are less likely to occur.

The one sided sex distribution of the reported cases is puzzling, but may diminish or disappear as more cases come to light.

### SUMMARY AND CONCLUSIONS

Four types of chest pain occurring in patients with mitral stenosis are described, and cases illustrating each type are reported. The types of pain are that of cardiac neurosis; that of acute rheumatic carditis, angina pectoris, and so called "hypercyanotic angina."

The literature bearing on hypercyanotic angina is discussed.

It is suggested that this type of pain is due to anoxia in a hypertrophic and overworked myocardium. This anoxia is explained as the combined result of severe organic changes in the pulmonary vessels, with pulmonary congestion and arterial anoxemia, in addition to reduced blood flow to the left ventricle and hence to the coronary arteries.

## THE SYNDROME OF CERVICAL RIB WITH SUBCLAVIAN ARTERIAL THROMBOSIS AND HEMIPLEGIA DUE TO CEREBRAL EMBOLISM\*

### Report of a Case

SIBLEY W. HOOBLER, M.D.†

BOSTON

IT IS not generally appreciated that thrombosis of the subclavian artery may in rare cases be the source of cerebral embolism. Symonds,<sup>1</sup> in 1927, reported 2 cases in which absent arterial pulsations in the right arm, apparently resulting from cervical ribs, had been complicated by the sudden development of left hemiplegia. His explanation was that "... pressure of the cervical rib upon the right subclavian artery led to thrombosis, that the thrombus extended backwards to the point of junction with the right common carotid, and a portion of it becoming broken off formed an embolus in one of the terminal branches of the right middle cerebral artery."

The fatal outcome in such a case was described one year later by Yates and Guest.<sup>2</sup> Their patient had complained of progressive pain and weakness of the right hand and forearm for some months. An absent arterial pulsation in the right upper extremity and an ununited fracture of the right clavicle were found. Before treatment could be instituted, the patient was taken suddenly ill with pain in the head and throat, loss of vision, unconsciousness, left hemiplegia progressing to quadriplegia, coma and death on the seventh day. Autopsy revealed an old ununited fracture of the right clavicle, with backward and downward displacement toward the right subclavian artery. This vessel was filled with an organized and very adherent thrombus, which extended to within 1.0 cm. of its junction with the right common carotid artery. A well-marked embolus was found at the division of the basilar artery into its terminal branches. The authors suggested that in this case the embolism had occurred through the escape of a fragment of the thrombus up the right vertebral artery.

More recently, Smith<sup>3</sup> has reported a similar case, in which the autopsy findings conformed even more closely to Symonds's original explanation of the course of the embolism. The patient, a twenty-two-year-old seaman, suddenly developed a left hemiplegia. He had occasionally complained of a mild, tingling sensation in the right arm and hand that had never incapacitated him. At the

time of the cerebral accident, no pulse could be obtained anywhere in the right upper extremity. Shortly thereafter, the patient lapsed into coma and died. Autopsy revealed a thrombosis of the right axillary and right subclavian arteries, apparently originating in a small, sacculated congenital aneurysm attached to the right axillary artery. The thrombus extended as far as the origin of the right common carotid artery, and a large embolus was found occluding the right internal carotid artery where it enters the carotid canal.

In a brief review of the literature, only one other case could be found that may represent the combination of events first recognized by Symonds. This was reported by Gould<sup>4</sup> in 1884. Although the author apparently did not recognize the pathogenesis of the symptoms, calling it a case of "obliterative arteritis," his description is very clear, and the clinical course similar to the case to be reported. It may be summarized as follows:

C. B., age 19, a laborer in a brickfield on the Isle of Wight, was admitted to the London Temperance Hospital on October 13, 1883. At the end of April, 1883, he noticed the fingers of his right hand getting "dark" in color. The hand seemed weak; when at work it quickly became cold and then there was a "sickening pain" in it.

State on admission: the limb below the elbow was distinctly colder than the opposite one. Just above the elbow all pulsation ceased. The radial artery was a prominent hard, pulseless cord. A great prominence of the right subclavian artery above the clavicle was noted; it projected under the skin as a tense pulsating cylinder which was bulging forward even beyond the level of the clavicle. Springing from each side of the lower two cervical vertebrae was found a hard, immovable, irregular mass apparently bony. When the subclavian artery was pressed against the mass in a particular direction, a thrill was produced in it.

In a second communication, three years later the author<sup>5</sup> stated:

This patient was shown to the Society two years ago. Since then he remained at work as a labourer until six months ago, when he was attacked with numbness in the right arm and forearm, accompanied by severe headache. . . . Four months ago he suddenly lost power in the left arm, and the same evening he became unconscious. Next day he spoke and moved his arm. He noticed the pulsation of his right subclavian artery until four months ago, not since.

\*From the Medical Clinic, Peter Bent Brigham Hospital, and the Department of Medicine, Harvard Medical School.

†Assistant resident in medicine, Peter Bent Brigham Hospital.

The right forearm is distinctly colder than the left. The axillary and the third part of the subclavian artery can be plainly felt as a hard pulseless cord.

The sixth reported case of this unusual complication of subclavian arterial thrombosis follows.

### CASE REPORT

D L, a 38-year old carpenter, was admitted to the Medical Service of the Peter Bent Brigham Hospital on February 3, 1941, with a history of weakness and inability to walk.

Two hours before admission, the patient had noticed sudden weakness of the left hand so that he had dropped his lunchbox twice, felt weak in the knees and had had to be assisted in walking to his place of employment. Because no improvement occurred after 2 hours, he was sent into the hospital.

Two years previously, he had come to the Out Door Department complaining of numbness, tingling pain and weakness in the right hand of 6 weeks duration. Examination had revealed weak right radial normal brachial and increased right subclavian arterial pulsations. Weakness and some atrophy of the muscles of the right hand had been noticed, without sensory impairment or decreased skin temperature. X-ray study revealed bilateral cervical ribs. At operation, it was noted that the subclavian artery lay higher than usual, presented a normal caliber and amplitude of pulsation, and did not appear compressed over the rib. Since the brachial plexus also did not appear unduly stretched, it was decided to cut the scalenus anticus muscle and not attempt resection of the rib. Complete symptomatic relief and considerable increase in the amplitude of the right radial pulsation had followed the operation until 6 months before admission, when the patient again complained of mild weakness and occasional paresthesias of the right hand and a decreased right radial pulse. These symptoms had been exacerbated in the 2 weeks prior to admission and he had in addition noted recurrent pains about the right shoulder and supraclavicular fossa.

The patient had enjoyed excellent health except for a brief attack of neuritis involving both upper arms 16 years before, and an episode of right facial weakness diagnosed as Bell's palsy 12 years prior to this admission.

At the time he was admitted to the ward, neurologic examination revealed a left hemiparesis and weakness of the left lower facial musculature. The deep tendon reflexes were increased on the left. Except for the facial weakness, the cranial nerves were intact. The pupils were equal and reacted well. There was no dysarthria or aphasia. Sensation was nowhere impaired. The Babinski and Kernig signs were absent.

The right radial and brachial pulses could not be detected and the axillary pulse was greatly diminished. However, pulsation in the right subclavian artery was increased. The blood pressure on the right could not be obtained, but in the left arm it was 120/70, and on this side arterial pulsation was normal. On palpation, no difference in the skin temperature of the two upper extremities could be noted, and there was no evidence of cyanosis or muscular weakness on the right side.

The heart was not enlarged to percussion. The rate was regular, 78 beats per minute, and no murmurs were heard. The remainder of the physical examination was likewise negative.

Laboratory data, which included routine blood, urine and stool examinations, lumbar puncture and skull films, showed no essential deviations from the normal. The Hinton and Wassermann reactions on the blood and spinal fluid were negative.

Following hospitalization, improvement in the neurologic findings was striking. The day following admission only moderately increased tendon reflexes on the left and a positive Barre sign bore witness to the patient's previous disability.

Five days after entry however he began to complain of pain about the right shoulder and numbness of the right hand. Overnight, the right subclavian artery had almost ceased to pulsate, and a hard tender, fusiform mass replaced the previously dilated and pulsating artery. At the same time the sedimentation rate, which had been 6 mm per hour on the day of admission, rose to 34 and 40 mm on the 5th and 6th hospital days. The oral temperature varied between 98.6 and 99.8°F, falling finally to below 99°F on the 11th day, when the sedimentation rate reached 19. The numbness and right shoulder pain gradually improved, the subclavian tenderness disappeared, and a faint pulsation continued to be felt up to the 16th day when the patient was discharged.

Dr John Homans, who saw the patient on two occasions expressed the opinion that sympathetic nerve irritation from the cervical rib had produced brachial arterial spasm, followed by secondary retrograde thrombosis of the subclavian artery. He advised against surgical intervention at that time, since adequate collateral circulation seemed to have developed. He concurred in the opinion that the cerebral episode was in all likelihood the result of embolism from the thrombus that had formed in the subclavian artery.

### DISCUSSION

In this patient, the symptoms of cervical rib had been present for two years and had recurred some months before the cerebral incident. At the time of the embolism, the subclavian arterial pulsation had been present, but an active ascending thromboangitis may be assumed from the diminished radial pulsation and the subsequent development of fever, local tenderness and almost complete obliteration of the pulse in the right subclavian artery. The sudden occurrence of left hemiplegia in an otherwise healthy man and its transient character are quite compatible with the diagnosis of a small cerebral embolism. This represents another case in which a thrombus, originating in the right axillary or subclavian artery, propagated itself toward the right common carotid whence a small fragment broke off to lodge in a branch of the right middle cerebral artery and thereby produced a transitory left hemiplegia.

In every reported case of this unusual syndrome, the thrombosis occurred in the right subclavian or axillary artery, and the cerebral lesion was also right sided. This is readily explained by the fact that only on the right does the common carotid originate with the subclavian from the innominate artery, so that only on this side of the body would a retrograde thrombus or embolus be caught in the

carotid blood stream and carried to the brain. Should thrombosis occur in the left subclavian artery, emboli would be carried into the aorta and lodge in places less likely to produce distinctive symptoms (Fig. 1). Embolic occlusion of the

FIGURE 1.

*This diagram illustrates the fact that an embolus from a retrograde thrombus in the right subclavian artery is likelier to enter the cerebral circulation than one from a thrombus in the left subclavian artery.*

basilar arterial branches, as reported by Yates and Guest,<sup>2</sup> could occur from thrombosis in the right or left subclavian artery, since the vertebral artery on both sides originates from the subclavian. The possibility remains that in the other cases embolism also occurred by way of the vertebral artery, passing by means of the posterior communicating artery into the circle of Willis and, finally, entering the middle cerebral vessels, instead of passing directly through the common carotid artery. This explanation is rendered unlikely by the small caliber of the posterior communicating artery, by the frequency with which the right side is involved, and by the infrequency with which emboli are reported to lodge in other branches of the vertebral artery. Furthermore, in Smith's<sup>3</sup> case, in which autopsy was performed, there was definite proof that the pathway of embolism was the carotid and not the vertebral artery.

The only other findings common to all the cases reported were a history of symptoms of cervical rib or vascular insufficiency over a period of a few months to six years, and an absence of right brachial or radial pulsation at the time of the cerebral accident. In most cases, the subclavian artery had also ceased to pulsate, but in one patient, thrombosis of this vessel did not take place until after the hemiplegia had developed. In no case did definite evidence of ascending thrombosis or thromboangiitis in the right subclavian artery occur immediately prior to the embolism.

It should be emphasized that this complication

of subclavian thrombosis is uncommon. In the files of the Peter Bent Brigham Hospital and the Boston City Hospital, no similar cases could be found, and the few isolated reports in the literature bear further witness to its rarity.

Although the conception of embolism originating from retrograde thrombosis of an obstructed artery is somewhat unusual, the occurrence of emboli from mural thrombi located in the wall of large arteries or aneurysms has frequently been reported. Lewis and Pickering<sup>6</sup> suggest that some of the peripheral symptoms of cervical rib may be due to small emboli coming from mural thrombi in the compressed wall of the subclavian artery. In the case reported by Girode et al.,<sup>7</sup> a fatal embolism at the aortic bifurcation was traced at autopsy to a thrombus in an aneurysm of the abdominal aorta. In Marcus's<sup>8</sup> patient, mural thrombosis in the descending aorta gave rise to four distinct embolic episodes. Wood<sup>9</sup> described a young man who complained of pain in the right shoulder, developed suddenly a cold pulseless right extremity, and died fourteen hours later following a left hemiplegia. At post-mortem examination, a walnut-sized aneurysm was found just proximal to the origin of the right common carotid artery, and thrombi were found in the right axillary artery and in the circle of Willis. Unfortunately, the report does not state whether a thrombus was found in the aneurysmal sac, which might have given rise to two separate emboli, whether the axillary thrombus might have been the source of a cerebral embolus, or whether both arteries developed thrombosis in situ.

## SUMMARY

A case of cervical rib is described in which retrograde subclavian arterial thrombosis, embolism to the right middle cerebral artery and a resultant left hemiplegia developed. Five cases with a similar syndrome, which have been reported in the literature, are reviewed.

MEDICAL DISCHARGES FROM MILITARY SERVICE<sup>1</sup>

## A Report of Six Hundred Cases

DAVID J. FLICKER, M.D.,<sup>†</sup> AND OLON H. COLEMAN, M.D.<sup>‡</sup>

CAMP BLANDING, FLORIDA

ARMY requirements provide that, when an enlisted man because of physical disability has become permanently unfitted for military service, he be retained in a hospital until his physical condition has reached such a point that he will not be benefited by further treatment in a military hospital.<sup>1</sup> When he has reached this condition of maximum benefit, a C. D. D. (Certificate of Disability for Discharge<sup>2</sup>) is prepared by his immediate commanding officer and forwarded to the commanding officer of the hospital, station or regiment in which the enlisted man is serving. On receipt of this certificate, the commanding officer convenes a board of medical officers, usually three, to examine the enlisted man critically and to enter on his certificate the required data. These data must include the origin and degree of disability, and must describe particularly the disability, wound or disease, and the extent to which it deprives the enlisted man of the use of any limb or faculty or affects his health, strength, activity, constitution or capacity to labor.

Such discharge is not recommended by this board when in their opinion the enlisted man, although mentally responsible, is incompetent or does not possess the required degree of adaptability for the military service, or gives evidence of habits or traits of character that make his retention in the service undesirable, and when the underlying cause for these characteristics is constitutional psychopathic state, morose state, mental deficiency, chronic alcoholism or drug addiction.<sup>3</sup> If, however, it is the opinion of the board of medical officers that the enlisted man is not mentally responsible, he is discharged with a certificate and in accordance to Army Regulation 600-500.

An honorable discharge<sup>4</sup> from the Army of the United States is given if the disability is received in line of duty. If the disability is the result of a man's own misconduct, occurring since or prior to enlistment, he is given a "blue" discharge. This is neither a dishonorable nor an honorable discharge. It is a discharge without honor. If the disability was noted on the enlistment paper, how-

ever, or the soldier merits an honorable discharge by reason of honest and faithful service for one or more enlistments since the occurrence of the disease that resulted in the disability, an honorable discharge is given.

It is apparent, therefore, that by the certificates of disability for discharge the Army may dispose of men who have slipped by induction boards and are unfit for military service.

It is also possible to return to civilian life soldiers who, because of mishap, are so injured or afflicted with disease as to be no longer of value in a fighting machine. As a matter of practice, the enlisted man is kept in the hospital wards until a complete and detailed medical workup is obtained. This may, and usually does, include many consultations, laboratory tests, x-ray films and whatever else the staff physicians deem advisable. The physician works with the ease obtainable in pure medical practice; and since no expense is spared, no financial problems are involved. All the medical knowledge, ability and equipment and all the nursing at the command of the hospital are utilized. Every effort is expended to return the soldier to the effective list. However, cases of failure perforce occur. Perhaps the man was admitted to the Army in error. He may not possess the proper qualifications for a soldier. He may have shown, subsequent to induction, epileptic seizures or psychotic or psychoneurotic traits that the inducing physicians were unable to detect. Before induction he may have had flat feet, nonsymptomatic, that subsequently started to cause pain; he may have been a good soldier and been injured with resultant loss of a limb or an eye or he may suddenly be discovered to have diabetes or other serious illness. These are but a few of thousands of possible situations that may necessitate relieving the soldier from military duty.

In Camp Blanding, we have been presented with an opportunity to study personnel from different parts of the country from the time of their induction into the Federal service. We have two divisions: the Thirty-first, or Dixie Division, comprises troops from Florida, Georgia, Mississippi, Alabama and Louisiana; the Forty-third, or New England Division, consists of troops from the six New England states. We present herewith the compiled abstracted data on the first 600 men to

<sup>1</sup>From the Station Hospital Camp Blanding (Colonel) Luther R. Foust (Camp Surgeon).

<sup>2</sup>Captain Medical Corps Reserve, Army of the United States.

<sup>3</sup>Major Medical Corps Reserve, Army of the United States Regular, 52nd Hospital, Camp Blanding.

<sup>4</sup>This group of cases is disposed of according to Army Regulation 615 3/4 Section VIII.

receive certificates. This survey includes the period from January 15 to July 21, 1941, inclusive.

Rate of Granting Certificates

Figure 1 shows how the rate of certificates has risen since the opening of the camp. The slow on-

FIGURE 1. Rate of C.D.D. Discharges.

The solid line represents the rates of discharge per thousand per annum; the dotted line, the camp strength in thousands.

set, with the sharp rise, must be interpreted as related to the difficulties encountered in getting the hospital routine established and in getting a smooth-

FIGURE 2. Age When Discharged.

ly functioning organization for the disposal of patients entitled to certificates. It must be remembered that the divisions involved were National Guard divisions that had insufficient knowledge of

Army regulations for the disposal of casualties. Many certificates were slowed down in the technicalities of regulations. Another factor of considerable weight is that no competent psychiatrist arrived in Camp Blanding until about March 15. This fact also accounts for the high percentage of organic cases in comparison with cases in which the psychic factors were of greatest importance. Of the 600 discharges, 464 disabilities (77.3 per cent) were listed as organic. The diagnoses "flat feet," "sacroiliac disease," "gastritis," and "tachycardia, persistent, etiology unknown," figured largely. Perusal of the charts revealed that many of these cases might more properly have been called neurocirculatory asthenia, gastric neuroses, psychogenic backache and so forth. One hundred and thirty-six men, or 22.7 per cent, were discharged for psychiatric reasons. These included such diagnoses as "mental deficiency" (42), "psychoneurosis" (63), "psychosis" (23) and others (8). Subsequent figures have shown that the discharges from psychiatric causes in a peacetime army may even exceed those from organic causes.<sup>4</sup>

Age

Despite popular conception to the contrary, the number of discharges did not increase with age, and the ratio of certificates to the number of men in each age group was quite constant. Figure 2 shows the actual number of men discharged in each age group. Figure 3 shows the percentage of discharges of each age group. This is compared with the percentage of men of each age in a random sample of 3000 soldiers.

Duration of Service

How long is it before a soldier manifests signs indicating his inability to fit into the military or-

ganization? How long does it take the Army to determine that a man is unfit to be a soldier? Figure 4 shows our findings. The significant fact is that the peak is at three months. Since in most cases

about six weeks elapse in the machinery of obtaining a certificate (complete hospital workup, holding of a board and obtaining of necessary endorsements), it can readily be seen that most men who are going to break down do so rapidly and are rather promptly recognized. Furthermore, in the reported cases, we believe that the lag after three

FIGURE 3 Percentages of Discharge by Age

The solid line represents the percentages of discharge by age, the dotted line, the percentages of camp population by age

months is attributable to the newness of the divisions in Federal service and the slowness in the establishment of the routine for obtaining certificates. It must be borne in mind that these divisions until quite recently were in the service of the various states and that the men trained one or two nights per week and, possibly, three weeks during

FIGURE 4 Months of Service before C D D

the summer each year. They had, therefore, a limited experience in the methods of the Army.

#### Previous Occupation

It was rather difficult to arrive at any definite conclusions regarding previous occupations. In the first place, each grouping had to be quite arbitrary.

Whether a farmer is to be considered an unskilled, semiskilled or skilled laborer is a moot point, and whether a truck driver who handles a trailer truck is unskilled or skilled is equally debatable. However, these questions were solved as seemed justifiable in each particular case. College students, lawyers, veterinarians, a physician (who was discharged for epilepsy and later committed suicide), a doctor of philosophy in chemistry and a chemist were in the professional group; merchants, store clerks and salesmen were placed in the business group. Table 1 shows the number

TABLE 1 Occupations of Men Receiving Certificates of Disability for Discharge

OCCUPATION	NO DISCHARGED	PERCENTAGE OF TOTAL DISCHARGES	PERCENTAGE OF 3000 SOLDIERS
Unskilled labor	244	37.0	28.7
Semi skilled labor	103	17.1	23.1
Skilled labor	131	21.8	20.2
Business	50	15.0	16.4
Professional	4	.6	9.6

of men in each occupational group who were discharged, the percentage each group contributed to the 600 discharges, and the percentage of men in each occupational group as taken from the previously mentioned sample of 3000 soldiers. It is apparent that the more educated and highly trained the person, the better his adaptability and the greater the likelihood of his being a successful soldier. It reminds one of a statement attributed to General Pershing, "The best citizens make the best soldiers." Furthermore, there was a considerable

difference in the reasons for the failures of the educated and uneducated.<sup>4</sup>

#### Rank

Among the noncommissioned officers, selection, both psychologic and physical, had already taken place to a great extent. Those who were dis-

charged usually had quite a duration of service and received certificates for physical disabilities that were frequently engendered in line of service. Very few of these noncommissioned officers were discharged with such diagnoses as "psychoneurosis." They were less frequently discharged, from a percentage basis in relation to their numbers, than the privates, and the ratio decreased with the increase in rank. This is quite obvious in Table 2, which shows the number of men in

TABLE 2. *Ranks of Men Discharged.*

RANK	No. Discharged	PERCENTAGE OF TOTAL DISCHARGES	AVERAGE PERCENTAGE IN ARMY
Private . . . . .	479	78.5	52.0
Private, first class . . . . .	57	9.5	30.0
Corporal . . . . .	38	6.3	10.0
Sergeant . . . . .	26	4.3	8.0

each grade discharged, the percentage of the discharges in each rank and the average percentage of men in each rank in the Army as a whole.

Type of Service

This camp is essentially an infantry camp, possessing only one field-artillery brigade and no cavalry units. Other troops include military police, a hospital detachment, a quartermaster corps and similar corps-area-service command troops. No significant relation could be found between the number of discharges and the type of military service performed, these figures standing approximately in direct ratio to the number of troops engaged. Thus, 400 certificates were contributed by the infantry, 88 by the artillery, and 112 by other groups. The type of military service could not be regarded as a contributory factor to medical discharge.

Urban versus Rural Population

Arbitrarily selecting all municipalities listed in the 1941 *World Almanac* that contain 2500 inhabitants or over as representing urban life, we divided the men in accordance with rural or urban origin (Table 3). The percentage of discharges

TABLE 3. *Discharges among Men from Urban and Rural Sections.*

SECTION	No. Discharged	PERCENTAGE OF TOTAL DISCHARGES	PERCENTAGE OF 3000 SOLDIERS
Urban . . . . .	108	18.0	32.4
Rural . . . . .	492	82.0	67.6

among men from rural sections was all out of proportion to the percentage of such troops in the Army, and leads one to the assumption that the

"stalwart farmer boy" may not be so good a soldier as his city brother.

Incidence by States

On July 25, the comparative strength of the two divisions was: the Thirty-first, 17,942 men, and the Forty-third, 16,483 men. By that date, there had been 149 certificates from the Forty-third and 410 from the Thirty-first Division, 41 being listed as from "other troops." Reduced to percentages, it had become necessary for the Thirty-first Division

TABLE 4. *Discharges by Sections and States.*

SECTION	TOTAL No. OF MEN	No. OF DISCHARGES
New England (43rd Division).	16,483	149 (0.64%)
Maine . . . . .		20
New Hampshire . . . . .		4
Vermont . . . . .		31
Massachusetts . . . . .		1
Rhode Island . . . . .		11
Connecticut . . . . .		82
South (31st Division) . . . . .	17,942	410 (2.29%)
Georgia . . . . .		17
Florida . . . . .		130
Alabama . . . . .		81
Mississippi . . . . .		90
Louisiana . . . . .		92

to discharge 2.29 per cent of its personnel whereas the Forty-third Division had released only 0.84 per cent. The number of cases by states is shown in Table 4. These are the states in which the men were inducted into military service.

Line of Duty

Of the 600 cases reported, only 8 were marked as "line-of-duty" discharges. In all the others, the notation was made that the disease or disability "existed prior to enlistment."

SUMMARY

An analysis of the first 600 cases relieved from duty at Camp Blanding under the Army regulation providing for certificates of disability for discharge is presented. The rate of discharges, the relation of organic to psychic factors as causes of disability, the age of enlisted men at the time, the duration of service prior to medical discharge, the relation of previous earned rank and type of service, whether the cases were urban or rural, and, finally, the geographical distribution by sections and states are given.

These statistics were collected during the formative period of the camp, and further studies may show substantial changes in some of these factors.

# ANTHRAX: REPORT OF A FATAL CASE INVOLVING THE CUTANEOUS AND GASTROINTESTINAL SYSTEMS\*

WILFRED D. MACDONALD, M.D.†

WORCESTER, MASSACHUSETTS

**H**UMAN anthrax, usually involving the skin is still an industrial hazard confronting workers in tanneries and wool industries and to a certain extent agricultural laborers. Since most industrial anthrax is of the cutaneous type and the reports of internal anthrax (pulmonary and gastrointestinal) in the literature are so few, the following case is presented.

## CASE REPORT

H S, a 38-year-old man, was admitted to the hospital on June 17, 1941, obviously dangerously ill. He had been employed for years in a Worcester brush factory where he handled bristles imported from China, India and Manchukuo.

Four days before admission the patient was seen at home by his physician who treated him for sore throat and swelling of the lymph nodes on the right side of the neck. He did not seem acutely ill at this time. However, he appeared much worse each day of his illness and a day prior to admission his face was markedly swollen, the pulse was of poor quality, and the temperature was subnormal. Moreover, the abdomen was tense and distended and very tender to pressure.

On the morning of admission the patient's condition grew critical at home, and he was referred to the Belmont Hospital with a tentative diagnosis of mumps. Meanwhile a pustule on his forehead aroused the suspicion of anthrax.

On admission the patient's temperature was 97.0°F and no pulse could be detected at the wrist. The respirations were 40 per minute and very labored. The patient was drenched in perspiration, the lips were cyanotic and there was a generalized, mottled cyanosis of the skin. He was rational and cooperative and complained of abdominal pain, inability to catch his breath and weakness in the forehead, just above the right eyebrow, was an area of redness about the size of a five-cent piece. This lesion was raised and indurated. Topping the lesion was a 4 mm. pustule with a central umbilicated hemorrhagic and necrotic area. The tongue was dry and heavily coated. The roof of the mouth was studded with eight to ten tiny yellow pustules. The pharynx was red and injected and heavy, greenish yellow exudate was noted in the postnasal space. There was a large brawny induration of the left side of the face and neck. This mass was hard and no pitting edema or fluctuation could be felt. The heart sounds were weak, —barely audible— and no murmurs were heard. The blood pressure could not be read. Nothing abnormal was found in the lungs. The abdomen was tense, tympanic and markedly distended with tenderness, with spasm over the entire upper abdomen. No palpable masses or viscera were felt. The extremities were mottled in appearance and very cold to palpation. There were no neurologic changes.

The diagnosis on admission was anthrax cutaneous type, gastrointestinal anthrax and anthrax bacteremia. The diagnosis was tentatively confirmed by direct smear of the purulent material from the lesion on the forehead. The blood culture taken on admission showed a heavy growth of *Bacillus anthracis* in 36 hours.

The patient was immediately treated for shock. He was given 1000 cc of 5 per cent glucose by vein and shortly thereafter 2 gm of sodium sulfapyridine also by vein. As soon as a suitable donor could be obtained the patient received 500 cc of citrated blood. Meanwhile a request was sent to Boston for 300 cc of specific anti-serum. After the transfusion the patient improved for a while but the pulse did not become perceptible. He was catheterized because of inability to void for about a day at home but only a small amount (70 to 25 cc) of very concentrated urine was obtained.

Examination of the blood showed a red-cell count of 5,500,000 with a hemoglobin of 90 per cent (Sahli), and a white cell count of 10,600. The urine showed a specific gravity of 1.073, acid reaction, the slightest possible trace of albumin and no sugar. The sediment showed a few hyaline casts and a few red and white blood cells per high power field. Smears and cultures of the lesion on the forehead were positive for *B. anthracis*. The nonprotein nitrogen was 19 mg and the blood sugar 143 mg per 100 cc.

The patient became progressively worse. He developed delirium about 5 hours after admission and died 1 hour later before serum could be obtained. Prior to expiration the patient vomited a large amount of coffee grounds, material mixed with bright red blood and he had a terminal rise in temperature to 103.0°F.

**Autopsy** (performed by Dr. Raymond Goodale of the Worcester City Hospital). There was an elevated skin lesion just above the right eyebrow. This lesion measured 1.2 cm in diameter with a 3.0 mm central depression. In addition a few golden yellow lesions were noted on the hard palate.

The lymph nodes on the right side of the neck were enlarged and the surrounding edema extended down to the clavicle on that side. The organs of the chest were grossly normal.

The abdominal cavity contained about 500 cc of cloudy, amber colored fluid. The mesentery contained a few hemorrhagic areas in which the fat was swollen so that it measured 5 cm in thickness.

The thoracic esophagus was normal. The stomach appeared grossly normal but contained 50 cc of coffee grounds material. Just below the ampulla of Vater was an edematous area in the mucosa measuring 6.0 cm in diameter and giving the intestinal wall a total thickness of 1.5 cm. The lesion was red and there was a glistening mucinous appearance on section. In the lower jejunum 170 cm from the duodenum was the second lesion which measured 1 cm in diameter. The third lesion located 200 cm above the ileocecal valve, measured 1.5 cm in diameter. The fourth lesion was 190 cm above the ileocecal valve and also measured 1.5 cm in diameter. The fifth and largest lesion which was located 170 cm above

\* From the Department of Contagious Diseases, Belmont Hospital.  
† Chief of the Department of Contagious Diseases, Belmont Hospital.

the ileocecal valve, measured 18 cm. in length; it was intensely red and swollen, and the mucosa showed signs of necrosis (Fig. 1). The final lesion was located 120 cm from the ileocecal valve, and was 15 cm. long; the mucosa was pink and swollen but no hemorrhage or necrosis was present. All lesions presented a mucinous appearance on section.

tract was undoubtedly the swallowing of large numbers of the spores. Lucchesi<sup>1</sup> points out that the mouth may be infected by contaminated hands.

The fatality rate from cutaneous anthrax is still high, 16 per cent being average mortality for the cases reported during the five-year period 1934-

FIGURE 1. *Lesions of the Small Bowel.*

*The upper specimen is a section of small bowel showing maximum involvement, with edema, hemorrhagic changes and early necrosis, the middle one shows the earlier changes, which consist of edema, a gelatinous exudate and some hemorrhagic changes, with no necrosis. The lower one is a section of normal small bowel.*

Anthrax bacilli were recovered from the cultures of the pus from the lesion on the forehead, of the free abdominal fluid and of the blood removed from the right auricle.

Microscopic examination of the mesenteric lymph nodes showed an acute, hemorrhagic adenitis, there were acute inflammation and edema of the ileum, a few anthrax bacilli being present.

#### DISCUSSION

This case represents a massive inoculation with *B. anthracis*. The cutaneous lesion occurs usually after contamination of an apparently healthy skin with spores of the anthrax bacillus. In the case presented, there was no history of previous trauma to the skin. Most writers, however, postulate a break in the skin before infection can take place.

The mode of invasion of the gastrointestinal

1938. However, this represents a 6 per cent reduction from the previous five-year period. Internal anthrax, on the other hand, is almost always fatal. Eurich<sup>2</sup> reports 23 cases of pulmonary anthrax that ended fatally. He had seen but one case of gastro-intestinal anthrax. Moreover, the recent literature does not report a single case of recovery from gastrointestinal anthrax. There is a possibility, however, that the outlook for internal infection will improve with newer methods of treatment, as evidenced by the recent report of Lucchesi and Gildersleeve,<sup>3</sup> who report 2 cases of recovery following anthrax bacteremia. Moreover, one of the cases was of the pulmonary type, which is usually rapidly fatal.

In the treatment of anthrax, several features stand out clearly. The recent investigators are apparently in agreement that local incision and excision of the anthrax pustule is contraindicated unless the lesion is very small and easily accessible for surgery. Moreover, the practice of local injection of serums around the lesion has been discontinued in most clinics.

Serotherapy, given intravenously and occasionally intramuscularly, seems to be indicated in all cases of anthrax. The method used is fairly large doses (100 to 300 cc.) given at twenty-four-hour intervals over a three-day period.<sup>3</sup> Neoarsphenamine given in 0.6-gm. to 0.9-gm. doses over this same three-day period has proved to be a valuable adjunct in treatment<sup>3</sup>; this may permit reduction in the dose of serum.

Recently, sulfanilamide and sulfapyridine have been used in the therapy of anthrax. In guinea pigs, according to Mitchell, Walker and McKercher,<sup>4</sup> sulfanilamide seems to control the spread of the anthrax infection; however, this drug has not

been used in a sufficient number of human cases to provide definite conclusions of its value. Bonnar<sup>5</sup> reports recoveries in 2 critical cases in which sulfapyridine in conjunction with serum and neoarsphenamine was used.

#### SUMMARY AND CONCLUSIONS

A fatal case of internal anthrax with bacteremia is reported, with autopsy findings.

Anthrax still remains an occupational hazard to workers in wool, hair and hides, in spite of rigid control of imported materials.

The prognosis of internal anthrax is grave in spite of the excellent results obtained in the therapy of cutaneous anthrax with specific serum and neoarsphenamine.

## MEDICAL PROGRESS

### VASCULAR DISORDERS OF THE EXTREMITIES (Concluded)

JOHN HOMANS, M.D.\*

BOSTON

#### POST-TRAUMATIC PAIN COMPLEXES

UNDER the titles "post-traumatic pain syndromes" (Livingston<sup>37</sup>), "reflex dystrophy of the extremities" (de Takats<sup>38</sup>), "trophoneuroses" and many others, these peculiar painful states have long been looked at askance by the profession in general as functional, perhaps hysterical, disorders. Recently, Homans<sup>39</sup> has discussed them under the title "minor causalgia" and has called attention to the fact that similar disorders may follow inflammatory thrombophlebitis of the legs. That painful, edematous states associated with paresthesia of the skin may arise from thrombophlebitis tends to confirm earlier impressions that such syndromes represent a vicious reflex arising from irritated peripheral vascular sensory-nerve fibers.

The minor causalgias are usually insurance problems and as such have considerable economic importance. The initial injury is usually trifling. A blow on the hand, forearm or foot, the wound of

a thorn, a burn, a frostbite, a minor fracture or sprain, a felon, a "milk leg," any of these may establish the reflex disorder. The hand is oftenest affected. Some part of it, usually a roughly anatomic field of one or more great nerves, is "dull" to pinprick, cool to the touch, slightly edematous (knuckle markings lost) and faintly bluish. The part feels "stiff," the grip is lost, and there may be some sensitive area—trigger point—that causes the patient to protect the part from all contacts. The severity and persistence of the causalgia vary greatly, but a hysterical element is rarely present and most of the victims desire to work.

The causalgia can usually be cured by the breaking up of the reflex, even temporarily, by the interruption of sensory impulses at the trigger point (Livingston), on the principal artery leading from the part, in the somatic nerve serving the part (Livingston) or in the sympathetic chain at the root of the affected limb. A single injection of procaine may cure. Repeated injections have a progressively good effect. Gentle measures and persistence are usually rewarded. Probably, surgery should not go beyond periarterial sympathectomy or paravertebral sympathectomy, al-

though excision of a sensitive scar or sinus is sometimes successful.

### THROMBOSIS IN DEEP VEINS OF EXTREMITIES

Within the last few years, the venous thromboses in the lower limbs have been separated into two classes: the quiet, nonobstructive, embolus-threatening sort, or *phlebothrombosis* (Ochsner and DeBakey<sup>40</sup>), and the outspoken, inflammatory, obstructive sort, or *thrombophlebitis*. The pathological studies of Neumann,<sup>41</sup> Frykholm<sup>42</sup> and Hunter et al.<sup>43</sup> have proved that in fatal cases (pulmonary embolism) the thrombosis, almost necessarily the quiet phlebothrombosis, originated in the venous plexuses among the muscles, particularly in those of the calf but sometimes in those of the foot or thigh. Venographic examinations, instigated by dos Santos<sup>44</sup> and greatly developed by Bauer,<sup>45</sup> have shown how the common, quiet process, complicating injury, operation or disease, or even appearing during active life (Homans<sup>46</sup>), may remain local or progress into the femoral vein. Here it may form a long, loose, fatal embolus or work its way centrally in a lightly adherent, nonobstructing form into the upper femoral or external iliac vein, or actually fill and block the latter vein, causing the familiar phlegmasia alba dolens of thrombophlebitis.

#### *Phlebothrombosis*

This relatively quiet process may be utterly silent until a serious embolism occurs. Or it may cause lameness (on walking), pain in the calf, full, slightly tense, tender muscles, discomfort on forced dorsiflexion — the dorsiflexion sign — and a varying degree of edema and cyanosis, which may be absent on elevation and only evident on dependency.

There is some difference of opinion concerning treatment. The statistical figures of Barker, Nygaard, Walters and Priestley<sup>47</sup> indicate that about one person in twenty in whom thrombosis is *recognized* will suffer an embolism whether or not fatal; and that one person in five, having experienced a pulmonary infarction, will die of a later embolism. As a result of their clinical experiences, Fine and Sears<sup>48</sup> recommend, as a routine procedure, exploring the femoral vein, to head off the embolism, remove the clot and so forth, whenever a diagnosis is made. Welch and Faxon<sup>49</sup> favor it. Welch, Faxon and McGahey,<sup>50</sup> by combining the routine use of venography with special clinical observations, have determined to their satisfaction the indications for femoral exploration and the management of thrombosis at various levels and stages. Homans<sup>51</sup> prefers conservative treatment in early cases, but opens and divides the

femoral or one of the iliac veins when embolism or recurrence of symptoms (after nonoperative treatment) indicates that healing without further accident is unlikely. For conservative treatment, he recommends 6-inch elevation of the foot of the bed, freedom of movement, no ice bag, no bending at the hip and, after ten to fourteen days of such elevation, gradual resumption of activity in a semielastic bandage.

The value of heparin is difficult to assess. Murray and Best<sup>52</sup> have shown that routine postoperative heparinization heads off thrombosis. Murray<sup>53</sup> points out that in a considerable series of cases, heparinization, instituted only after pulmonary infarction had already occurred, prevented further embolism\* (an important observation in view of the percentage of deaths following a preliminary infarction recorded by Barker et al.<sup>47</sup>). Heparin may be given as a continuous intravenous drip (Murray and Best) or every four hours, in a dosage of about 60 mg. of purified heparin, constantly checked by the clotting time (capillary-tube method). The expense is at least seven or eight dollars a day even without special nursing. When surgery is not available and especially when expense is not a problem, heparinization seems indicated. A clotting time of ten to twenty-five minutes should be maintained for three to five days and then tapered off, to avoid the danger of recurrent thrombosis.

Dicoumarin, whose use is in the experimental stage, has recently been put forward as an anticoagulant. Provided it is efficient and not harmful, the fact that it can be given by mouth gives it an advantage over heparin. Unlike heparin, whose action can be stopped immediately on neutralization by protamine, dicoumarin, once in the circulation, cannot be neutralized, and transfusion of blood is not always a satisfactory means of control of the dicoumarin effect. Dicoumarin lengthens the clotting time materially only after being administered for several days, and its action continues for several days after it has ceased to be given (Davidson<sup>54</sup>). Thus, present information indicates that caution should be used in the acceptance of dicoumarin as a satisfactory substitute for heparin in such situations as those for which heparin is now known to be valuable.

#### *Thrombophlebitis*

Irrespective of its origin, that is, whether it begins in a thrombosis low in the leg, in the uterine veins or locally in the femoroiliac region, thrombophlebitis, phlegmasia alba dolens or "milk leg" is an obstructive process in which an inflammatory exudate often surrounds the femoral and iliac veins

\*Although no figures comparable with Murray's are available, deaths from embolism under similar circumstances have occurred in very much smaller series in the experience of other surgeons.

and arteries. Some degree of local arterial spasm, as already noted, results. (Experimentally, the effect on arterial blood flow of a local irritation within and about a large vein is described by DeBakey, Burch and Ochsner.<sup>7</sup>) Also, as a reflex, a diffuse peripheral vasospasm in the arterioles or venules, or both, perhaps, occurs. The resulting edema is due partly to venous obstruction, partly to lymphatic obstruction and partly (in some cases almost exclusively) to the peripheral vasospasm. This list has been Leriche's<sup>56</sup> contribution, and following his observation that lumbar sympathetic procaine block relieves the edema in a remarkable way, Ochsner and DeBakey<sup>7</sup> have fully discussed the pathologic physiology and have popularized this treatment.

The special indications for making use of a sympathetic block are edema, fever and discomfort (as signs of a perivascular irritation). But routine conservative treatment should still be carried on. This consists in elevation of the foot of the bed, without immobilization of the leg, and the use of a heated cradle, to promote vasorelaxation. Ice bags should not be applied. Sympathetic block is most effective if used early. The technic is based on one or another of Labat's<sup>57</sup> methods of securing a paravertebral anesthesia, but adapted by White<sup>9</sup> to reach the sympathetic chain just ventral to the lateral curve of the vertebral body. Ochsner and DeBakey<sup>7</sup> introduce three needles (4 inch lumbar puncture needles, with stylets) through wheels placed respectively about two fingerbreadths (roughly, 4 to 5 cm.) lateral to the midline of the back and opposite the first, second and third lumbar interspaces. Each needle, entering perpendicularly to the plane of the back, should strike a transverse process at a depth of about 4 or 5 cm. The needle is then redirected above or below the process and somewhat medially, meeting next the lateral border of the vertebra. Another readjustment in a more lateral direction carries its point to glide past the vertebral belly for perhaps 1 cm into the region of the gangliated chain. Five to ten cubic centimeters of a 1 per cent procaine solution is injected through each needle.

On the basis of Flothow's<sup>58</sup> recommendation of Lundy's<sup>51</sup> method, others (Reichert,<sup>59</sup> de Takats<sup>60</sup> and Homans<sup>61</sup>) prefer to introduce a 4 inch (for women) or 5 inch (for men) needle, with stylet, 7 cm lateral to the midline opposite the first lumbar interspace. This spot is near the twelfth rib and the outer margin of the erector spinae muscles. The needle is directed toward the midline at an angle of about 35° from the perpendicular. A transverse process may or may not be met at a depth of 4 or 5 cm, the plan being to strike the broad lateral curve of the vertebra at a deeper

level. The needle is then partly withdrawn and redirected more laterally so that it glides just past the vertebral belly. This method increases not only the chances of placing the needle point close to the sympathetic chain which lies toward the front of the vertebra, but also the risk of injuring the aorta (on the left) if the needle is thrust too deeply. However, if it is passed no more than 1 cm beyond its last bony contact and meets no resistance in that last step, an arterial injury is extremely unlikely. Suction should always be made, however, before injection, to make sure no vessel has been entered. If any bleeding occurs, the needle should be withdrawn and reinserted at a higher or lower level.

**Postphlebotic pain complex.** Postphlebotic pain, associated with paresthesia below the knee and some degree of edema and cyanosis, may remain after a femorofemoral thrombophlebitis, a causalgia-like state (Homans<sup>62</sup>). Lumbar sympathetic block, performed during the acute stage of thrombophlebitis, tends to ward off this sequel. In many cases, one or more sympathetic blocks often cure the pain complex itself. The favorable effect of one block should not be allowed to lapse before the next block is given. Thus, in time, even an obstinate process may often be relieved. If not, sympathectomy combined with lysis of adhesions between the iliac vessels on the affected side—or even resection of the diseased vein—is likely to succeed (Leriche and Geisendorff<sup>63</sup>).

## VARICOSE VEINS

### Etiologic Factors

The causative factors of varicose veins have been studied by Adams<sup>64</sup> from the point of view of venous pressures and the effect of valvular incompetence. By means of direct pressure determinations in the normal great saphenous vein, Adams found that the presence of normal valves did not alter the transmission of pressures in the fluid system and that such pressures followed Pascal's law, namely, that "pressure applied to an enclosed fluid is transmitted equally in all directions and acts with equal force on all surfaces." Thus, pressures at any one level represent the weight of the column of blood between that level and the heart. Adams points out that when the patient is upright the resulting high pressures in the leg tend to overstretch the superficial veins unprotected by surrounding muscle. So long as valves remain competent, however, additional pressures from above, caused by straining and lifting, can raise pressure within the saphenous system little if any higher than gravity itself can do. But once the valves become incompetent, the effect of straining and lifting is to raise superficial venous

pressure in varicose veins to pathologic levels. In such veins, as is well known, pressure may rise to high arterial levels. Adams then makes some interesting inferences:

"Recannulization" (Adams's word) will occur after treatment by injection unless a high preliminary division is carried out. High division should not be condemned because pressures in the remaining varices below are not lowered, for all that high division can do is to prevent the additional elevation of pressure due to straining and lifting.

Adams advises the inclusion, in the Trendelenburg test for varicosity, of a consideration of the additional effect, beyond gravity alone, of straining.

Veal and Hussey<sup>67</sup> have made direct examination of pressures in the popliteal veins of pregnant women. They studied especially the effect of exercise to be sure that the engorgement of exercise should be given consideration. As between subjects having respectively normal and varicose (or edematous) legs and between the normal and varicose leg of one pregnant woman, popliteal pressures remained stationary on exercise in the normal leg and rose decidedly in the varicose. They conclude that local venous obstructions within the pelves of some pregnant women have led to varicosities by causing pressures higher than normal in the veins of the legs and that, in selected cases, support of the superficial veins during pregnancy by an elastic stocking or bandage should be advantageous.

Edwards and Edwards<sup>68</sup> have continued their interesting observations on the valves of the veins in the legs. In earlier communications, they<sup>69</sup> discussed the orientation of valves in relation to the body's surface, and the destruction of valves by thrombosis. Now they show how overstretching of the vein's wall causes valves to become useless. They present models of cross sections.

### *Tests for Varicosity*

There is an evident tendency in some clinics to make rather elaborate tests of varicosity. Mahorner and Ochsner<sup>70</sup> have developed elaborations of the Perthes test (observation of the state of filling of superficial veins below an elastic constriction during exercise) to demonstrate obstruction or normalcy of the deep veins and also the presence of incompetent perforating veins at some particular level. So far as the situation of incompetent communicating veins is concerned, the tests of these authors, if intelligently and skillfully performed, show the need for accurate dissection and division of perforating veins in particular patients and particular localities. Experts can well use them for this purpose. (It should be noted that elaborate tests of deep venous obstruction in the presence of

varicose veins are unnecessary. For since varicose veins will not transmit blood upward in the standing position, a normally colored foot in the dependent varicose leg on standing or exercise guarantees a normal deep venous return. Moreover, blocking or removing varicose veins should *always* lighten the load of the deeper system irrespective of the state of that system.)

Pratt<sup>71</sup> regards undiscovered and undivided incompetent communicating veins as a common cause of recurrence after high division and retrograde injection of varicose veins. He considers the Mahorner-Ochsner tests to be "difficult to perform and to interpret and . . . so time consuming that they were not useful in the clinic." He proposes a test that uses the constricting rubber tube about the upper thigh to prevent down-flow through the saphenous vein and applies a bandage from the toes up to the level of this constriction. As the leg is lowered and this bandage is removed by degrees from above, the location of incompetent communicating veins or "blowouts" is revealed. He recommends that such blowouts be surgically corrected. (It is questionable whether the incompetent communicating vein, which Pratt and others describe as a "blowout," affords so direct and open a leak from the deep veins to the varicose superficial ones as is pictured. Anatomic studies made many years ago [Jarjavay<sup>72</sup>] show that alternative routes between the deep and superficial systems are available and are usually able to conduct blood in or out according to local pressures in one system or the other. Thus, although the communicating veins normally conduct blood from surface to depth, some, or all, of them are subject to local pressure influences, through the action of by-passes. Undoubtedly, attention *should* be given to gross leaks outward into varicose veins, and these ought to be considered in planning surgical treatment. But normally high pressures in the postoperative, varicose system are consistent with competent as well as incompetent communicating veins. In this connection, Adams's<sup>66</sup> communication is significant, and pathologically high pressures, that is, on straining and coughing, are far likelier to be re-established, in that part of a varicose system left below a high division, by a reconnection of varicose vessels at the groin than by the communicating veins of the lower leg.)

### ELEPHANTIASIS

A very ingenious and useful contribution to the surgery of elephantiasis has been made by Macey.<sup>73</sup> In a patient with a great congenital hemangiolymphangioma of the arm, a procedure involving the burying of a split graft in the muscle of the fore-

arm and beneath the greatly deformed lymphangiomatous, superficial tissues was attempted. At the end of two weeks, the superficial parts were dissected from the surface of the graft, which had healed perfectly. Only a little loose connective tissue was left between the skin graft and the muscle. Evidently, the forearm and the back of the hand were treated in two stages, although the operator, in describing the first operation, makes the almost incredible statement that the "lymphoedematous, subcutaneous tissue was dissected from the musculature of the forearm in a completely encircling manner."

Undoubtedly, the principle can be applied to the not very uncommon, disabling elephantiasis nostra, or praecox, of the leg, particularly by the aid of the huge and uniform "half" and "three quarter" thickness grafts that Padgett's<sup>74</sup> machine is capable of cutting. If such means prove suitable for covering the deep parts of the whole lower leg, the ankle and the front of the foot, they should prove superior to the procedure of replanting great attached flaps of pure skin on the subaponeurotic structures (Homans<sup>75</sup>), by which half the lower leg and foot can be treated at a sitting. Similar plastic flap operations have been used by Knott,<sup>76</sup> who has had a wide experience with the tropical form of the disease. Knott has also devised most ingenious ways of compressing, by various bandaging devices, the elephantiac leg and finds that, after the leg has been reduced to an approximately normal size, not only are the inflammatory attacks eliminated but a plastic operation is made relatively easy.

Macey's communication, valuable as it is, contains one or two statements that can hardly be allowed to pass unchallenged. He states

The original conception of the Kondoleon operation, that of establishing a communication between the superficial and deep lymphatics, has been discarded and it is now felt that the superficial lymphatics drain directly into the vascular network of the muscles after removal of the deep fascia. On microscopic examination sections of normal muscle have been demonstrated to have abundant lymphatics and from the clinical observation, the lymphatics in the muscles seem involved by the lymphedema.

As to the first of these statements, there is no evidence of any sort that, as a result of a plastic operation, fluids collected between the skin and the deeper structures are carried into spaces between the muscles or that such vascular network as may be present can absorb the highly proteimized tissue fluids of elephantiasis. And as to the second, namely, that abundant lymphatics exist in muscle, there are, it is true, some lymphatics in the intermuscular fibrous tissue of normal persons, but

that lymphatics exist in the muscle proper, there is no convincing proof (Drinker and Yoffey<sup>77</sup>). Apparently, in fully developed elephantiasis, no valved lymphatics are left in the limb. If any tissue fluid passes centrally between the muscles, it must be forwarded by muscular squeezing and pumping. It is not necessary that subaponeurotic lymphatics be present to make a radical plastic operation safe in elephantiasis. In the elephantiac leg, fluid passes through wide spaces in the fibrosed superficial tissues by gravity alone. Such tissue fluids as remain after most of the subcutaneous tissues have been excised probably drift between skin and the underlying muscle, or even in the skin itself, as elastic pressure and gravity direct. Some years ago, Gillies and Fraser<sup>78</sup> implanted pedicled flaps containing lymphatics (from the arm) on the elephantiac leg, with the idea of draining its fluids into a part of the body where absorption was normal. Recently Pratt and Wright<sup>79</sup> have proposed a similar procedure. Even aside from the technical difficulty and dubious success of such elaborate plastic operations, the plan of excising the fluid-bearing, subcutaneous tissues seems decidedly more practical.

## CASE 28241

### PRESENTATION OF CASE

A fifty-three-year-old, single female office worker was admitted to the hospital because of jaundice of a month's duration.

About ten years before entry, the patient began to suffer from recurrent attacks of "indigestion," characterized by belching, epigastric distention, nausea and vomiting. These spells, which tended to occur after meals of fatty foods, continued sporadically for about six years, although the patient went on a low-fat diet, on the advice of her physician. In the three years preceding entry, she remained quite well, and gradually returned to a full diet. Two months before entry, she experienced a constant sense of pressure in the epigastrium, lasting for about two weeks. This feeling was aggravated by deep respiration and was not accompanied by any other symptom. A month before entry, the patient noted that her stools were clay colored. In the next week, generalized pruritus appeared, and the urine became deep orange yellow. She was given "vitamin K and bile salts" and was put back on a low-fat diet. The symptoms continued to progress, with the addition of weakness and lassitude. The appetite was only fair in the month preceding entry, and in this time she lost 14 pounds in weight. At no time was there nausea, vomiting, pain, chills or fever.

A younger sister of the patient had had an operation for "gall-bladder disease," and a brother had died in childhood of typhoid fever. The patient thought that she herself had had a transient attack of jaundice as a child. She denied the use of alcohol and of drugs other than those specified. Six months before entry, she had a normal menopause.

On admission, the patient appeared well developed and nourished, and in some distress from diffuse pruritus. There was evidence of recent weight loss. The skin and scleras were icteric, and all over the body there were multiple excoriations from scratching. The heart and lungs seemed normal. A smoothly rounded, slightly tender mass, approximately 5 cm. in diameter and fixed on respiration, lay in the right upper quadrant of the abdomen. The liver edge was not felt.

The blood pressure was 148 systolic, 105 diastolic. The temperature, pulse and respirations were normal.

Examination of the blood showed a red-cell count of 3,960,000 with 11.3 gm. hemoglobin, and a white-cell count of 4600 with 72 per cent polymorphonuclears, 12 per cent small lymphocytes, 12 per cent monocytes and 4 per cent eosinophils. The blood Hinton reaction was negative. The van den Bergh reaction was biphasic, with 24 mg. bilirubin per 100 cc. of serum. The hematocrit was 40 per cent. The prothrombin time was elevated to about four times normal. The serum protein was 6.2 gm., and the nonprotein nitrogen 28 mg. per 100 cc. The blood sugar was 70 mg. per 100 cc. The urine was dark amber, with a ++ test for bile pigments. The stools were clay colored, with negative reactions for bile pigment and for occult blood.

The patient was given Klotogen, Bilein and Hykinone, with a fall in the prothrombin time to normal. The temperature remained normal. On the seventh hospital day, an operation was performed.

### DIFFERENTIAL DIAGNOSIS

DR. WYMAN RICHARDSON: To summarize this case very briefly, the patient for ten years had symptoms consistent with gall-bladder disease, and then developed an obstructive jaundice and right-upper-quadrant mass. One is forced to make a diagnosis of cancer involving probably the gall bladder on the basis of pre-existing cholelithiasis. I should stop there. I shall go on, however, and add one or two things. In the first place, I had a case like this a year ago—in a fifty-three-year-old woman with a similar history—in which an indefinite right-upper-quadrant mass was disregarded because the patient was obese. I should have paid attention to it because she had a tumor of the biliary tract. In the case under discussion, the mass was definite, and I wonder if I am going to be misled about it again.

One can assume this mass to be gall bladder. One can also assume that the patient had gallstones and that she had a gallstone impacted in the cystic duct, with hydrops of the gall bladder, and another stone impacted in the common duct, with obstruction to the biliary flow. I should say parenthetically that there is no doubt that she had obstructive jaundice with complete obstruction. Of course, it is said that a palpable gall bladder is rare in the presence of common-duct stone. In other words, if this mass had been gall bladder, it would have ruled against the presence of stone. One other bit of evidence is that the mass is said to have been fixed on respiration. Ordinarily, I think

the gall bladder would tend to move on respiration. If it was gall bladder and if it was fixed, can that be taken as evidence of tumor of the gall bladder that has extended to surrounding structures and thus caused fixation? The only other evidence that I can glean from the record is the tendency to leukopenia—a rather curious blood formula for a leukopenia in that the polymorphonuclear cells were at a normal or slightly high level, the lymphocytes were decreased, and the monocytes were increased. This is not the ordinary type of leukopenia. Whether one can lean very much on that observation, I do not know. In cirrhosis of the liver, a leukopenia is common, and this might be evidence that the patient had an underlying cirrhosis. The mass felt might have been an abnormal lobe of the liver, and there might have been a tumor of the liver on the basis of underlying cirrhosis. That seems to me to be arguing quite far afield on slim evidence.

There is no mention of a palpable spleen, and in cases of cirrhosis of the liver without splenomegaly not much leukopenia is found. Occasionally, this blood formula is seen in lymphoma, more commonly with a slight increase in lymphocytes, rather than a decrease. I think that again is very slim evidence. In the patient whom I saw a year ago, the white-cell count as I remember it was between 9000 and 10,000.

I shall mention one more thing regarding the leukopenia. If there had been an impacted stone in the cystic duct, the chances are that there would tend to be some fever, presumably dependent on rather low-grade inflammation, and we might expect to have at least a slightly elevated white-cell count and slight fever.

One always ought to bear in mind the possibility at any age of toxic hepatitis, so-called "catarrhal jaundice." I remember having had a patient operated on for obstructive jaundice due to stone, I thought, who proved to have nothing but benign catarrhal jaundice. The mass that was felt in the case under discussion rather rules out this diagnosis. One would expect to feel a tender liver in a case of jaundice caused by toxic hepatitis. This mass is not spoken of as being very tender. I mention this because one should always think of it, but I cannot see any really good reason why this patient should not have been operated on for the purpose of establishing a definite diagnosis and also with the hope of being able to re-establish some form of biliary drainage, and to rule out the possibility that a stone caused this condition. With the setup as we have it, I come back to my original diagnosis: that this patient had a chronic cholecystitis and cholelithiasis and that as a result, as

sometimes happens, she developed a carcinoma of the gall bladder that extended to involve the biliary tract.

DR. JACOB LERMAN: Are you disturbed at all by the fact that the mass was smooth, if the examiner was accurate in his description?

DR. RICHARDSON: No, I do not believe I am. I am no more disturbed by his calling it smooth than I would be impressed by his calling it irregular.

DR. WILLIAM B. BREED: Nor by the fact that it did not move on respiration!

DR. RICHARDSON: That is a little more definite.

DR. BREED: Yes, but mistakes are made on that point just as often as on the other.

#### CLINICAL DIAGNOSIS

Carcinoma of head of pancreas.

#### DR. RICHARDSON'S DIAGNOSES

Chronic cholecystitis.

Cholelithiasis.

Carcinoma of gall bladder.

#### ANATOMICAL DIAGNOSES

Carcinoma of pancreas.

Cholelithiasis.

Hydrops of gall bladder.

#### PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: This patient was explored, and a huge distended gall bladder was found in which were many small stones and a large amount of colorless bile. The exploration was continued, and a firm mass was palpated in the pancreas, which was biopsied and showed carcinoma. The gall bladder itself did not show cancer. There was then a distinct problem in the surgical relief of this patient. Originally, it was believed that cholecystgastrostomy might be done, but with white bile in the gall bladder, it seemed probable that the cystic duct was obstructed and that such an operation would therefore be ineffective. Fortunately, the common duct was markedly dilated, and it was possible to anastomose the common duct successfully to the duodenum. The gall bladder was emptied of its stones and likewise drained. The patient made a fairly comfortable postoperative recovery, and the jaundice, though still present, was steadily diminishing at the time she left the hospital.

A PHYSICIAN: Was x-ray treatment given?

DR. MALLORY: I do not know. There is no mention of x-ray treatments in the record. If they are being given, I am sure it is with no enthusiasm.

## CASE 28242

## PRESENTATION OF CASE

A sixty-five-year-old Russian tailor was admitted to the hospital because of loss of weight and appetite.

The patient was in good health, except for occasional bouts of sinusitis, until about six weeks before entry, when there was gradual onset of weakness and anorexia. Constipation appeared, requiring enemas every third day. The stools were dark, but not bloody. There was no distention of the abdomen and no pain. Seven pounds in weight was lost. Ten days before entry, a local physician diagnosed "anemia," and prescribed iron and vitamin pills. No improvement followed this medication. In the week before entry, some cramping was noted in the abdomen.

The family history was irrelevant. Four years before entry, the patient had a large thrombosed hemorrhoid excised in the emergency ward of the hospital. He had also been treated for sinusitis, on two occasions, in another department of the hospital.

On admission, the patient appeared well developed, but rather undernourished. The heart was normal. The right lung field was clear, but many moist inspiratory rales were heard at the left base. The abdomen appeared full. No free fluid or masses were palpable. There was some hypogastric tenderness, but no spasm. Peristalsis was hyperactive, with high-pitched sounds. The prostate was of normal size.

The temperature was 99.5°F., the pulse 80, and the respirations 20. The blood pressure was 100 systolic, 55 diastolic.

Examination of the blood showed a white-cell count of 21,700 with 78 per cent polymorphonuclears, 9 per cent large lymphocytes, 5 per cent monocytes and no abnormal cells. The red-cell count was 4,010,000. The serum protein was 4.5 gm. per 100 cc. The chlorides were 102.5 milliequiv. per liter, and the nonprotein nitrogen 39 mg. per 100 cc.

A roentgenogram of the large bowel after a barium enema showed no evidence of obstruction. The cecum was high, and the sigmoid was rather redundant. Two diverticula projected from the descending colon. On re-examination, numerous dilated loops of small bowel were noted close to the cecum, suggesting a lesion at the ileocecal valve. Roentgenograms of the upper gastrointestinal tract showed some deformity of the duodenal cap suggestive of old duodenal ulcer. There was definite obstruction to the passage of barium by an irregular, apparently ulcerated mass in the upper jejunum. The loops of small bowel below this level appeared filled with air.

A Miller-Abbott tube was passed, and a blood transfusion was given. The temperature rose to 101.5°F., and then dropped to normal. On the third hospital day, an operation was performed.

## DIFFERENTIAL DIAGNOSIS

DR. E. PARKER HAYDEN: The history, at its outset, with a loss of weight and appetite of six weeks' duration, certainly suggests cancer. I shall exclude the possibility of cancer of the stomach simply on the failure of the X-ray Department to state that the stomach itself showed any abnormality when examined.

The onset of constipation six weeks before entry may or may not mean anything. Perhaps the patient was eating lightly or had shifted to a low-residue diet. The stools were not bloody. There was no distention of the abdomen and no pain. The serum protein was low, but the chlorides were normal. The nonprotein nitrogen was moderately elevated. The findings in the left chest may or may not be of much significance in an elderly person. The onset of definite cramps and hyperactive peristalsis indicates that the patient had mechanical obstruction on admission to the hospital, but on the other hand, the presence of some fever indicates infection — which is primary and which secondary, we must decide. The x-ray report states that there were dilated loops of small bowel close to the cecum. Whether these happened to lie close to the cecum, or actually involved the terminal ileum, is not certain. The diverticula in the descending colon, I suspect, were merely coincidental and, as so often happens, were probably not concerned in this picture.

We have evidence of an ulcerative mass in the jejunum and also evidence of obstruction near the ileocecal valve. The problem is to decide whether these findings were due to one lesion, perhaps primary at the ileocecal valve with adherence and involvement of a loop of jejunum, or whether there were two independent lesions. If there were two independent lesions, the condition might have been regional ileitis, or there might have been two independent cancers. It is difficult to be sure. Anemia and loss of weight are very common early symptoms of carcinoma of the cecum before localizing symptoms develop, and the subsequent onset of obstruction could readily have been due to involvement of the ileocecal valve with tumor. That diagnosis seems probable. The mass involving the jejunum could have been primary, or involvement secondary to a tumor in the ileocecal region. The localized loops in the region of the cecum also suggest the possibility of a herniation of small bowel through some aperture in the region of the cecum, a condition met with occasionally. However, I think I shall make a diag-

nosis of carcinoma of the cecum, at the ileocecal valve, with secondary involvement of the jejunum.

DR. RICHARD SCHATZKI: I do not know whether the record states emphatically enough that the films show no evidence of disease in the colon. The cecum is well outlined. There are several dilated loops of small intestine in the lower abdomen.

DR. HAYDEN: I was making some allowance for the fact that the roentgenogram does not always reveal lesions in the cecum.

DR. SCHATZKI: I think the fluoroscopy note, together with the films, is enough evidence against a lesion in the cecum. The upper gastrointestinal tract shows this ulcerated lesion in the first or second loop of jejunum, which has the definite appearance of malignant tumor. Some moderately but, I should say, definitely air-filled loops of small intestine are visible below this region, indicating additional involvement of the bowel below the region of ulceration. I do not see any films showing the small intestines filled with barium lower down, not because the small intestine was obstructed but apparently because such films are not here or they were not taken.

DR. HAYDEN: The loops described in the report, then, happened to be lying close to but were not concerned with the ileocecal valve.

DR. SCHATZKI: Not so far as there is evidence in the film. If there was a lesion there, it was in the small intestine.

#### CLINICAL DIAGNOSES

Intestinal obstruction.

? Lymphoma of intestine.

#### DR. HAYDEN'S DIAGNOSIS

Carcinoma of ileocecal region, with second involvement of jejunum.

#### ANATOMICAL DIAGNOSIS

Lymphosarcoma, multiple, of jejunum ileum.

#### PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: At operation, it was found that this patient had multiple tumors of small bowel. Each of these was several centimeters in length, and in each one the wall of bowel was uniformly thickened all the way around its circumference. There was ulceration of mucosa. The tumor masses were extremely friable, and in the course of exploration one of them spontaneously ruptured. It therefore became necessary to do a fairly extensive resection, and eventually received three separate segments of bowel, which contained several tumors. On microscopic examination, all showed a rather undifferentiated type of lymphosarcoma. The patient died two days after operation.

## IMMEDIATE NEED FOR MEDICAL OFFICERS

All who were present at the annual banquet of the Massachusetts Medical Society and who listened to the speeches of Dr. Frank H. Lahey and Dr. Morris Fishbein appreciate the immediate need for medical officers in the Army of the United States. This crisis was referred to also by Dr. John F. Fulton in the Shattuck Lecture, when he stated that, by the end of this year, the air forces of the Army and Navy will be expanded to include about 20,000 flight surgeons and medical officers. In other words, NOW is the time to volunteer—not six months from now, or even a month from now. Furthermore, if a sufficient number of

medical officers are not obtained by this means, there is every indication that more drastic measures will be taken to secure them.

The response in Massachusetts has been disappointingly slow, owing in a large measure to the erroneous impression of some physicians that the enrollment forms of the Procurement and Assignment Service are equivalent to applications for commission and to the fact that the information contained on these forms necessarily requires a considerable period before it can be tabulated and, hence, become available for use by the recruiting personnel of the armed forces.

To facilitate matters, as outlined in an editorial in the May 14 issue of the *Journal*, recruiting boards for medical officers have been established in all states. The office of the Massachusetts Medical Officers' Recruiting Board is located at 319 Longwood Avenue, Boston (ASP 3638). These boards, working in conjunction with the Procurement and Assignment Service, are authorized to commission directly a qualified physician in the Medical Corps of the Army, provided he is declared "available" by the state or local officers of the Procurement and Assignment Service; in such a case, the physician will be assigned to active duty within a few weeks following his application. In addition, the boards will forward applications for commissions from graduates of unapproved and foreign medical schools to the Office of the Surgeon General for individual consideration.

To repeat, the enrollment forms of the Procurement and Assignment Service are NOT applications for commissions. Furthermore, this governmental agency will NOT tell physicians what to do—whether to go, or when to go; its function consists only of acting in an advisory capacity to the armed forces and of determining whether physicians are "available" or "essential." This IS the call, and all qualified physicians in Massachusetts should IMMEDIATELY apply, through the Medical Officers' Recruiting Board, for a commission. After the war is over, let it be said that Massachusetts physicians VOLUNTEERED their services.

## INDUSTRIAL HYGIENE AND THE WAR

THE recent joint meeting in Washington, D. C., of the National Conference of Governmental Industrial Hygienists and of the Subcommittee of Industrial Health and Medicine, Health and Medical Committee, Office of Defense Health and Welfare Activities, brought out many problems that are of vital interest in the present emergency.

The five major points raised by various speakers were as follows: workers, individually and collectively, should serve as the fulcrum of all efforts to improve industrial health; the efficacy of medical, engineering and chemical controls of occupational hazards has been proved; knowledge, experience and organization are such that time-loss due to disability can be greatly reduced; threats to the health of war workers have increased, in many parts of the country, to a critical, or even desperate, stage; and to meet this emergency,—that is, to avert disaster and to establish a condition of vigorous health among all workers,—all the facilities for prevention and restoration must be expanded.

Figures released by the War Production Board showed that seven and a half million people are now employed in producing the implements of war and that double that number will be needed by the end of the year. This marked increase will intensify existing problems and will create new ones. For example, the need for medical and nursing services in small plants, which now employ about two thirds of the industrial population and which, as a rule, fail to provide such services, will be even more acute. Furthermore, the employment of women will present difficulties that require a new approach, as will the introduction of new toxic substances, and longer working hours with shorter periods of relaxation.

State industrial-health officers praised the aid furnished by the Government—both financial and otherwise—and affirmed that they had the knowledge and the spirit markedly to decrease loss of time due to disability; however, they acknowledge that they were tremendously handi-

capped by a lack of personnel—physicians, engineers, chemists and nurses.

Since the outcome of the war depends on the production of its instruments, all agencies—federal, state and industrial—must co-operate in every possible way to increase productive efficiency by improving the health of war workers. And, after the battle has been won, this service, which is the fundamental right of the millions of industrial workers in this country, should be continued.

## MEDICAL EPONYM

### PFEIFFER BACILLUS

"Vorläufige Mittheilungen über die Erreger der Influenza [Preliminary Notes on the Etiologic Agents of Influenza]" was published by Richard Friedrich Johann Pfeiffer (1858), while he was a *Privatdozent* in the Institute for Infectious Diseases at Berlin, in the *Deutsche medicinische Wochenschrift* (18:28, 1892). A portion of the translation follows:

In all the cases [31] of influenza, a distinct variety of bacillus was found in the characteristic purulent bronchial secretion. These rods were demonstrable in absolutely pure culture and usually in tremendous numbers in the cases of uncomplicated influenza. . . . The rods were found only in influenza. . . . The numbers of the bacilli kept pace with the course of the illness. . . . Numerous inoculation experiments were attempted. Positive results can be obtained only in monkeys and rabbits.

### COMMITTEE ON MATERNAL WELFARE

#### CASE HISTORY: TOXEMIA FOLLOWED BY ANURIA AND DEATH

A twenty-eight-year-old primipara, when approximately thirty-five weeks pregnant, entered the hospital with marked edema, a blood pressure of 164 systolic, 92 diastolic, a trace of albumin and a sediment containing many granular and hyaline casts. She had been followed by her physician from the beginning of pregnancy and had shown no abnormalities until about the thirtieth week, when albuminuria appeared. The blood pressure was said not to have risen for another month. The past history was irrelevant; there had been no contagious diseases or any operation. The patient was treated at home for a week before she entered the hospital. Two days after admission, because of a sustained systolic blood pressure of 160 to 170

and a diminution in the urinary output, labor was induced with a Voorhees bag. The bag was expelled twenty four hours later, and an infant, presenting by the breech, extracted. The baby weighed 5 pounds, 12 ounces, and lived only a few hours. Anuria developed immediately after delivery, and the patient died forty eight hours later.

**Comment** Although the care of this patient was adequate, it was not of the most intelligent nature. If she had been hospitalized at the onset of her symptoms, and if rest in bed and a diet of  $2\frac{1}{2}$  quarts of milk a day (with absolute restriction of salt) had been instituted, improvement might have been noticed. If, under hospital care and constant surveillance, edema had increased, the blood pressure had remained stable or increased, and the urinary output had decreased, delivery might well have been considered earlier. The use of the Voorhees bag for induction warrants no criticism. It is barely possible that rupture of the membranes alone would have achieved the same end, and that if an abrupt rise in the blood pressure had occurred during the hospital stay, an immediate cesarean section might have saved the baby and lessened the degree of nephritis that resulted in anuria and death.

Some cases of anuria developing in association with hypertension and toxemia, particularly those in which separation of the placenta (which this patient did not have) occurs, have been successfully treated by decapsulation of the kidney, but this treatment is not so satisfactory when applied to this type of anuria as it is for that following incompatible blood transfusion.

## DEATH

**POPOFF**—**CONSTANTINE POPOFF, M.D.**, of Haverhill, died May 30. He was in his sixtieth year.

Born in Bulgaria, Dr. Popoff received his degree from Harvard Medical School in 1910. He was a lieutenant colonel in the United States Army Medical Reserve, and at the time of his death was awaiting orders to active service. He was a member of the New England Roentgen Ray Society and the Radiological Society of North America, and a fellow of the Massachusetts Medical Society and the American Medical Association.

He is survived by two daughters.

## WAR ACTIVITIES

### CIVILIAN DEFENSE

#### BLOOD AND PLASMA BANKS

Regulations for the administration of the Blood and Plasma Bank Program of the Medical Division of the United States Office of Civilian Defense have now been prescribed, and funds are available for grants to assist approved hospitals in establishing blood and plasma banks. Only hospitals within three hundred miles of the Atlantic Pacific and Gulf coasts are eligible for such grants. After July 1, 1942, these geographical restrictions may be modified so that grants may be made to inland hospitals. Ap-

plications should be addressed to the Chief Medical Officer, United States Office of Civilian Defense, Washington, D. C.

Technical manuals on blood and plasma banks, prepared by the Subcommittee on Blood Substitutes of the Division of Medical Sciences, National Research Council, are now available for distribution on request of any hospital to the Chief Medical Officer, Office of Civilian Defense.

The Red Cross has established eighteen donor centers in various parts of the country, which are successful in obtaining an adequate supply of blood donors for military purposes. Blood for the production of dried plasma for civilian-defense purposes will also be obtained from these sources.

Hospitals that establish their own blood and plasma banks with the financial assistance of the Office of Civilian Defense are advised to build up their reserves of blood and plasma by expanding blood collections from relatives and friends of patients who are to receive transfusions. A public campaign for volunteer donors which might compete with the work of the Red Cross should be avoided if possible. If public solicitation is necessary, hospitals should appeal to the local chapters of the American Red Cross for assistance in recruiting hospital donors. Blood donor campaigns by agencies other than the Red Cross will tend to confuse the public and may interfere with the blood collection by the Red Cross for the armed forces.

The official release dated April 17, 1942, of the Federal Security Agency and the United States Public Health Service is as follows:

Whereas on April 11, 1942, there was allotted from the 'Emergency Fund for the President' to the United States Public Health Service the amount of \$292,500, to be expended by said Public Health Service in connection with emergencies affecting the national security and defense for procuring and establishing either independently or, subject to regulations to be promulgated by the Surgeon General, by grants to public and private hospitals located not more than three hundred miles from ocean or Gulf Coast, reserves of liquid, frozen or dry blood plasma or serum albumin for the treatment of casualties resulting from enemy action, the following regulations are promulgated to govern the administration of this allotment:

#### SECTION I ELIGIBILITY FOR GRANTS

Preference shall be given to hospitals serving communities whose geographical location implies a likelihood of civilian casualties from enemy action, and which are inadequately equipped to handle such casualties.

To be eligible for a grant a public or private hospital located not more than three hundred miles from ocean or Gulf Coast (the Appropriation Act for the year 1943 may not limit grants to hospitals within this geographical area) shall

(1) Have a capacity of not less than 200 beds, exclusive of bassinets provided that two or more smaller hospitals totaling 200 beds may submit a cooperative project designating one of the participating hospitals as the grantee,

(2) Be on the approved list of the American College of Surgeons and the Hospital Register of the American Medical Association, and

(3) Have on the professional staff a physician whose qualifications are the equivalent of those

required by the American Board of Pathology for its diplomates.

## SECTION II. APPROVAL OF PLANS

A grant shall cover a period of not more than twelve months following the approval of the plan, or not beyond June 30, 1943, and may be used only for the purchase of equipment necessary for the preparation of liquid or frozen plasma, reconditioning or minor alterations of existing quarters, necessary travel and subsistence allowance of \$6.00 per diem to cover a training period, if required, of not more than one week, for the physician directing the blood-plasma project, and temporary salaries of personnel necessary for the establishment of a blood and plasma project.

The maximum grant for one hospital is \$2000.

A hospital desiring to receive a grant shall submit a plan to the Chief Medical Officer, United States Office of Civilian Defense, who is authorized to receive such plans on behalf of the Surgeon General of the United States Public Health Service. A plan shall contain the following information:

- (1) The number of hospital beds classified according to use;
- (2) The name and qualifications of the physician who will direct the plasma project;
- (3) Description of present blood and plasma project, if any;
- (4) The type and amount of plasma reserves which the institution desires to prepare;
- (5) The delivered price of equipment necessary to complete the existing facilities for preparing such plasma — such items to be numbered and described in accordance with the equipment inventory in *A Manual on Citrated Normal Human Blood Plasma*, issued by the Office of Civilian Defense, or equivalent approved substitute equipment.
- (6) The materials or labor, if any, needed for adapting existing quarters to the needs of the blood plasma project; and
- (7) The salaries, if any, to be paid additional personnel until the plasma reserve has been prepared. Salary items shall also show the proposed periods of employment for each individual and the proposed monthly rates of pay.

When a plan is recommended by the Chief Medical Officer of the Office of Civilian Defense for the approval of the Surgeon General, the hospital will be furnished a budget and acceptance form to be signed, notarized and returned to the Chief Medical Officer, Office of Civilian Defense.

## SECTION III. CONDITIONS OF GRANTS

The hospital shall agree to build up a plasma reserve of at least one unit per bed within three months after delivery of the necessary equipment. A unit of plasma is that amount derived from 500 cc. of citrated whole blood, consisting of about 250 cc. of liquid plasma.

The agreed amount of plasma reserve shall be maintained for use without charge and only for treatment of casualties caused by enemy action. The reserve shall be released for use in other local hospitals for this purpose on order of the local chief of Emergency Medical Service and for transfer within the state on order of the state chief of Emergency Medical Service,

or transfer from one state to another on the order of the regional medical officer, Office of Civilian Defense.

Liquid plasma shall be kept from being outdated by replacement of older by newer plasma. Replaced units may be utilized for current needs of the hospital in the treatment of its regular patients, provided the plasma reserve shall not be allowed to fall below the stated minimum.

All plasma shall be prepared in accordance with manuals of the Office of Civilian Defense prepared by the Subcommittee on Blood Substitutes of the National Research Council.

The hospital shall agree to continue the plasma project for its current needs after the expiration of the federal grant and to maintain for the duration of the war the minimum stated reserve; thereafter the reserve may be used by the hospital without restriction.

A record shall be kept of all blood donors, including their blood types, to expedite obtaining donors for emergencies.

No funds made available under the grant shall be used for the payment of blood donors.

Any blood plasma project under this program shall be subject to inspection by authorized representatives of the Surgeon General of the United States Public Health Service.

## SECTION IV. METHOD OF PAYMENT

Payments will be made on a reimbursement basis for expenditures made in accordance with the approved budget. Applications for reimbursement shall be notarized and addressed to the Chief Medical Officer, United States Office of Civilian Defense. The procedure for payment will be as follows:

(1) Payments from the allotment to cover the purchases of nonexpendable equipment aggregating \$300 or more will be paid upon receipt, from the authorized administrative head and accounting officer of the hospital, of an itemized statement of the purchases supported by invoices showing the date of delivery of such equipment;

(2) Payments will be made for the authorized training expenses of the physician who is to direct the blood plasma project whenever the hospital presents a notarized claim itemizing the travel and per-diem allowance incident to the training;

(3) Reimbursement for other items of the approved budget will begin only after actual production of blood plasma is started. During the first three months of production, reimbursement will be made on a monthly basis and quarterly thereafter for the duration of the grant. Such reimbursement will be made only upon receipt of a report form prescribed by the Surgeon General from the institution showing expenditures incurred during the period, total plasma prepared during the month, and the total reserve on hand to date;

(4) Payments may be withheld, and plasma produced as part of this project may be transferred by the Surgeon General, from any hospital which fails to meet the conditions of the grant or to comply with the regulations;

(5) Each hospital shall submit monthly reports during the period of the grant showing the amounts of plasma on hand and used — thereafter, for the duration of the war, the hospital shall submit such reports quarterly on its use of the plasma; and

(6) Hospitals shall submit promptly reports including clinical abstracts of any untoward experiences encountered in the use of plasma for the duration of the war

## MISCELLANY

### NOTES

The Committee on Faculty of Middlesex University has announced the appointment of Dr Ernst Mathias to the professorship of pathology in the School of Medicine, to fill the vacancy caused by the recent death of Dr Leon A. Balduf. Dr Mathias was born in Königsberg Germany and studied at the Universities of Heidelberg and Königsberg, receiving his M.D. degree from the latter in 1912. He served as a member of the Department of Pathology at the University of Königsberg and at the University of Breslau, and was decorated three times for his services in the medical corps during World War I. Returning to teaching, he became professor of pathology in the medical school of the University of Breslau, and pathologist of the Jewish Hospital in that city. He visited the United States first in 1937, when he received an honorary fellowship in pathology from Yale University. He was forced to leave Germany by the Hitler regime, came to this country permanently in 1938, and received an appointment as pathologist in hospitals at Northampton, Holyoke and Greenfield. Dr Mathias is a member of the American Association of Pathologists and Bacteriologists and of the New England Pathological Society.

Middlesex University graduated a class of eighty-six from the School of Medicine at commencement exercises held on June 1 in Waltham. Congressman Thomas H. Eliot delivered the commencement oration. Dr Stephen Rushmore, dean of the school, presented the candidates and the medical degrees were conferred by President C. Ruggles Smith.

At the annual meeting of the New England Society of Physical Medicine, held at the Ring Sanatorium and Hospital on Wednesday, June 3, the following officers were elected: Dr Arthur L. Watkins, of Boston, president; Dr Wilmot L. Marden, of Lynn, first vice-president; Dr David C. Diamore, of Boston, second vice-president; Dr William D. McFee, of Boston, secretary; Dr Howard Moore, of Boston, treasurer, and Drs Charles W. McClure and Frank B. Colloten, of Boston, counselors for three years.

## REPORTS OF MEETINGS

### EVANS MEMORIAL HOSPITAL

At an Evans Lecture at the Evans Memorial Hospital on January 23, Dr Alfred Blalock, of Baltimore, spoke on "The Pathogenesis and Physiology of Traumatic Shock."

Shock is a manifestation of vascular failure, which may be cardiac or peripheral vascular in origin. Syncope of cardiac origin, as exemplified by the Stokes-Adams syndrome or any reflex slowing, such as that caused by a sensitive carotid sinus, is characterized by bradycardia and fainting. Its onset is sudden, and its duration is short, as contrasted with cardiac collapse. The cause is myocardial trauma of any origin whether from coronary artery disease, diphtheria or tamponade. There is abrupt tachycardia. In cardiac shock, there is usually congestion of

some part of the vascular tree, either peripheral or pulmonary, in contradistinction to peripheral vascular shock. Both types may have coldness, sweating and palpitation, and an acute cardiac shock may be difficult to distinguish from peripheral vascular shock.

By definition shock is a condition in which peripheral vascular failure is brought on by a discrepancy between the existing vascular bed and the circulating blood volume which leads to tissue anoxia. Shock may result from an increase of the vascular bed or a decreased circulating volume or a combination of both. The last is probably the commonest kind. The characteristics of early shock, which is the optimum time for treatment, are hemoconcentration, rapid pulse and low blood pressure. The last manifestation is late and is not comparable with the others for early recognition. However a chart of the blood pressure over a period is the best way of evaluating the status of an established case of shock. Of 2 patients with equal blood pressure readings the one with warm extremities who has not yet called on his vasoconstrictor apparatus has a better prognosis than the one with cold extremities whose sympathetic-adrenal system has already reacted maximally.

The remainder of the discussion was concerned with secondary or hematogenic shock, in which there are vasoconstriction and an increased vascular bed. Studies reveal that immediate gross hemorrhage causing death of an animal results in none of the tissue changes considered characteristic of shock, for there is apparently no time for its development. Slow bleeding however, produces changes similar to those of shock, as evidenced by the fact that transfusion of more than the lost volume of blood after a prolonged period of lowered blood volume and blood pressure will not save the animal. The tissues become hyperemic and necrotic. Dunphy and his associates have shown by early sacrifice of animals after trauma or burns that there is no capillary damage, much loss of fluid or tissue necrosis. But shock from all causes has identical terminal tissue lesions, so that it is only by study of early cases that any differentiation can be made.

Shock may be caused by many things, but the most important are toxemia, local fluid and blood loss and nervous trauma. The reason for most of the controversy is a failure to recognize that this syndrome cannot be explained by one mechanism. Experimentally, furthermore, there is a discrepancy in terminology, method of producing shock, anesthetic used, species difference and criteria of shock. Dr Blalock employs the method of trauma using one lower extremity but imputes higher than formerly—that is at the midabdomen. In such animals, there is a local loss of fluid at or near the site of trauma amounting to half the body volume, and this is the cause of shock. The seriousness of this local fluid loss is also borne out by longer experiments on bowel handling, which allows for possible accumulation of toxic products. Here, the loss is plasma rather than whole blood. In burns 3 per cent of the body weight may be lost locally, and a similar loss in normal dogs is sufficient to cause death in twenty-five hours. This may not be the only cause but it is the most important initial one in early deaths from burns which are most numerous. Other factors, such as sepsis enter into later deaths. And since burns are causing a large percentage of deaths in the present war, the necessity of finding a satisfactory method of preventing excess local fluid loss is evident. Some form of tanning is advisable for flat surfaces.

Experimental work is being carried out on the so-called crush syndrome, but so far this has been of little practical value. However, such injuries are not rare in people

pinned for long periods under debris of bombed buildings. The main differences between the experimental animals and crushed people are the immediate changes in the former on being released in contrast with the later changes in man. In animals, those treated by pressure to the part survived in 14 out of 17 cases, whereas the control group had only 1 survival in a similar number. This was in spite of an elevated hematocrit reading and fluid loss. Therefore, treatment should consist of constant pressure to the part, with an elastoplast bandage or tourniquet to prevent excessive fluid loss in the part. Blast injuries are known to be fatal in certain cases in which no evidence of any direct trauma is present. About 40 to 50 per cent of fatalities from this cause show no signs of direct violence (Hatfield). Such persons reveal widespread pulmonary hemorrhages but not of such magnitude as to cause death by compression. In animals subjected to such forces, similar bilateral pulmonary hemorrhages are found. A blast may cause similar injuries to the brain if the head is movable, and may result in intracellular neuronal disturbances. However, such cerebral damage is considered to be an exaggerated feature by some observers.

Acute circulatory failure may be classified as hemogenic (hemorrhagic), neurogenic (spinal) or vasogenic (histamine). In the last two, the cardiac output decreases before the blood pressure, whereas in the vasoconstriction following hemorrhage and trauma to muscle, the blood pressure drops first. The degree of hemoconcentration is proportional to the loss of blood or plasma.

In the treatment of shock, adrenocortical extract is theoretically useful but does not seem to have lived up to expectations practically. A pure oxygen intake, although likewise based on good logic, has not proved practically valuable. The application of heat is advisable if the person is in the cold or has just been brought in, but the great value of heaters and blankets in the usual case seems overemphasized. Experimentally, there have been more and longer survivals of animals left relatively cold. Furthermore, there has been this same improvement in results with the local application of cold, despite the same degree of fluid loss. Granted that the amount of heat supplied was physiologically excessive, it does seem illogical to use heat, which draws blood to the part from more vital centers. When the circulating volume is therapeutically increased, the addition of heat is apparently not contraindicated. Regarding parenteral fluid administration, it was emphasized that large amounts of crystalloids not only are lost but also wash out with them large amounts of plasma protein, thus decreasing the osmotic pressure, and are, therefore, definitely deleterious. Transfusions are dangerous if incompatibilities exist, and this is another indication for the use of plasma or serum. Patients die of loss of blood volume rather than of erythrocytes.

In dangerous degrees of shock, hemoconcentration may sometimes not be found. The pulse rate is often of little value, whereas the blood pressure is a fair but late indication of shock. It is still the best gauge of response to therapy. A clinical evaluation of the situation based on the severity of the injury and the amount of blood loss is often more valuable than the blood pressure. In other words, one should not wait for changes in pulse, blood pressure or hemoconcentration before initiating shock treatment. One should never administer more than 1500 cc. of saline solution daily.

Thus, it is seen that the mechanism of certain types of shock is understood, such as the local loss of tissue fluids, but that there are many others. In general, an attempt should be made to replace the same kind of fluid as that lost. The use of whole blood is contraindicated only

when hemoconcentration is a prominent feature, as in burns. Plasma and serum are available and very useful. Cohn's albumin appears to be a hopeful blood substitute. This is a nonantigenic, hypertonic solution.

#### WILLIAM HARVEY MEDICAL SOCIETY

At a regular meeting of the William Harvey Medical Society of Tufts College Medical School at the Beth Israel Hospital on January 30, Dr. Chester S. Keefer spoke on "The Epidemiology of Hemolytic Streptococcus Infections." The early recognition that a single organism was responsible for the many diseases attributed to the hemolytic streptococcus was made difficult by the multitude of clinical manifestations, but it is now generally accepted that this is a single organism.

Hemolytic streptococcus infections account for 5 to 10 per cent of all sickness and cause about 70 per cent of infections in wartime, burns and the puerperium. In crowded communities, such as war camps, it is surpassed only by measles and epidemic influenza. It is the commonest cause of bacteremia, as well as the commonest initiating factor in acute glomerulonephritis and in recurrences of rheumatic fever. Fortunately, there has been a great improvement in treatment in the past few years with the advent of the sulfonamides.

Some advances have been made in the epidemiology of hemolytic streptococcus infections, but knowledge is still far from complete. This is especially true of the control of its spread, and methods at present are inadequate. Predisposing factors include age and season of the year. Between five and fifteen years is the commonest period for most streptococcal infections attributable to the throat, whereas puerperal fever is commonest from twenty to forty years of age. The incidence of erysipelas, on the other hand, is greatest under ten and over forty years of age. The seasonal prevalence in New England—the winter months from December to March—parallels the incidence of respiratory infections. Any wound is likely to develop some degree of infection if the normal skin barriers are interrupted. This is particularly true of burns and war wounds. Mortality rates are highest under four years of age.

The modes of spread are many. The normal habitat is largely in the throat and nose. Carriers are commonest in the winter. Infection may be transmitted by contact, hands of patients, droplets through the air and dust, and fomites in the form of clothing, food and toys. Autoinfection is not rare. Five to thirty per cent of the population are carriers of the hemolytic streptococcus, but only about a third of these harbor the significant Group A organism. The carrier state is commoner in children than adults and varies with the season, crowding, contacts and the number of respiratory infections.

Classification, as carried out by blood-agar methods, has resulted in Groups A to H, whereas in Group A there are more than twenty-eight types determined by agglutination (Griffith) and precipitation (Lancefield). The soluble products of the hemolytic streptococcus are the erythrogenic toxin, hemolysin (streptolysin), leukocidin, fibrinolysin and a spreading factor. All have been shown to be antigenic, except leukocidin, which probably is, and the spreading factor, about which little is known. The cellular components are as follows: an M substance, which is type specific and is used for the production of antiserum; a T substance, which is separable by agglutination; a C substance, which is a group-specific carbohydrate; an N.P. substance, which is a nucleoprotein and is not even species specific; and hyaluronic acid, which forms part of the cap-

sule but is not antigenic. The experienced observer can usually tell the groups from blood agar plates, but it is better to use precipitation methods with specific antisera. The type specific M substance of Group A organisms, unlike that of the pneumococcus and other organisms, is protein in character.

The most characteristic sources of Group A are human infections, of B, bovine mastitis, of C, most animal streptococcal diseases, and of D, cheese and the human body (enterococci, certain saprophytes, organisms occasionally encountered in endocarditis and Ludwig's angina). Some of the higher groups are found in pneumonia, sinusitis, agranulocytic angina, some normal human beings, milk and dogs.

There are certain well-defined phases of streptococcal infections: a toxic phase, lasting from three to seven days and causing scarlet fever and so forth, a septic phase, lasting three to seven days or longer and causing severe localized reaction and only occasional bacteremia, such as the septic sore throat, a latent phase, lasting from ten days to six weeks in which an apparently normal convalescence is marred by a recrudescence, and a late non-suppurative phase, which may last from a few days to an indeterminate length of time. The last manifestation consists of fever, lymphadenopathy, nephritis, edema, cardiac insufficiency, arthritis, splenomegaly, with hepatomegaly, and erythema nodosum. At present, there is no adequate method for preventing or protecting against this phase of the infection. There may be only a persistent low grade fever following a sore throat, and the origin may not be discovered except by the taking of an electrocardiogram. There may be edema and cardiac insufficiency without true acute glomerulonephritis, and cerebral edema, with hypermagnesemia, may occur. Convulsions may be controlled by magnesium sulfate. It is best to prevent this phase, if possible, because of the danger of permanent cerebral damage. The toxic phase may be very acute and severe, but may be controlled with large amounts of antitoxic serum. This form of therapy, however, may merely serve to relieve the toxicity temporarily while allowing septic manifestations, such as acute otitis media. In this way, the septic phase not infrequently merges into the toxic. The sulfonamides have decreased the bacteremic mortality from 75 to less than 20 per cent.

Over a period of two years in a large general hospital, 95 per cent of the streptococcal cases were caused by Group A, whereas Groups B and C were responsible for only rare human illnesses. Group B has been identified in cases of puerperal fever, endocarditis, pyelonephritis, diabetes, pneumonia, meningitis and arthritis. Of the cases studied, by far the largest number were scarlet fever (414), followed by tonsillitis (120), otitis media and mastoiditis (131), and then by a great variety of other diseases. Of the scarlet fever cases, 75 per cent were caused by five types of streptococcus, which caused 53 per cent of the other miscellaneous infections. Types 15 to 17 caused 36 per cent in the former and 22 per cent in the latter group. This prevalence of types varies with the year, community and country, but in any one outbreak in a community there is one or a small number of streptococcal types. Therefore, tracing of cases by typing is not difficult if the number is small.

In a study of multiple cases of scarlet fever in families, the same type in a family was found in 100 per cent of 10 cases and only six different types were found in all 36 cases. Therefore, spread undoubtedly occurred by actual contact. Examination of the types in streptococcal complications reveals that the same type as that of the original

focus is frequently (in 11 out of 12 cases) found in less than two weeks, whereas it is infrequently so (in 3 out of 18) after two weeks. It may be concluded, then, that later complications are largely the result of cross infection in a ward or hospital, and thus, therefore, be comes an important public health problem. Typing methods may be used to advantage in tracing cases. Strict isolation and segregation of the same types in scarlet fever and other epidemics should be carried out if at all possible or practical.

At the present time, control of infection with the hemolytic streptococcus may be approached by the isolation of the patient, the tracing of the source, and the observance of strict surgical asepsis in patients with wounds, burns and puerperal infections. At least 70 per cent of wounds and burns develop such an infection in the first week, probably from other patients, attendants, clothes and dust. The highest bacterial counts in the air occur in the morning, when beds are made and the wards cleaned, and dressings should preferably be postponed to another time.

## BOOK REVIEWS

*Handbook of Communicable Diseases* By Franklin H. Top, M.D., M.P.H., and collaborators. 8°, cloth, 682 pp., with 73 illustrations and 10 color plates. St. Louis: The C. V. Mosby Company, 1941. \$7.50.

This is a sound, up-to-date book on the diagnosis, treatment, general management and prophylaxis of all the communicable diseases, with particular attention to the public health angles involved. Anyone who needs such a book, and who does not own one, will do well in buying this. The only question that arises is, in a field already so well supplied with adequate texts, was there any real need to add another to the list? Most authors along this line are in substantial agreement, and the reviewer cannot help believing that there is small profit in rehearsing, in more or less stereotyped fashion, matters already sufficiently well covered in most libraries.

*The Proceedings of the Charaka Club* Volume X. 8°, cloth, 270 pp., with 9 plates and 34 figures. Baltimore: The Williams and Wilkins Company, 1941. \$5.00.

This volume contains a selection of papers read before the Charaka Club during the years 1937 to 1940. Of particular interest is a paper on the early years of the club, by Dr. Bernard Sachs, one of the original members. A timely publication is that of Dr. Walter R. Steiner on the experiences of a physician in the United States Sanitary Commission during the Civil War. There are twenty-one other papers, mostly representing the literary interests of physicians.

*Training and Efficiency* By E. J. J. Kl, E. H. Cluver, C. Goedvolk and T. W. De Jongh. 4°, boards, 188 pp., with 28 illustrations and 18 plates. Johannesburg, South Africa: The South African Institute for Medical Research, 1941. 10s. 6d.

This book is a study, made by the South African Institute of Medical Research, of 32 standard army recruits, presumably a fairly representative cross section of a large group of youth in that political division of the Continent. It was undertaken to determine if, by compulsory training, this class of the citizenry could not be raised to a level of efficiency that would permit of their being classified as useful members of society.

One of the results of this study was to show that this substandard condition is not the outcome of fundamental biologic defects but rather is due to environmental conditions. Primarily, the physical fitness of a large proportion of Europeans in South Africa was lamentably low, and very many of the subjects had not the initiative to overcome this condition.

It appears from the success of this experiment that there is very good reason to think that by means of compulsory physical training, supplemented by appropriate occupational instruction, the labor power of this section of society may be greatly increased and that the opinion, so often expressed, that this class is "utterly degenerated" may thus be completely refuted. As a sociologic study, the book deserves to be read, and its recommendations should be heeded.

*The Therapeutics of Internal Diseases.* Vol. IV and Vol. V. Supervising Editor: George Blumer, M.A. (Yale), M.D. Associate Editor: Albert J. Sullivan, M.D. 4°, cloth. Vol. IV, 790 pp., with 56 illustrations, 22 tables and 2 charts. Vol. V, 765 pp., with 29 illustrations, 31 tables and 1 chart. New York: D. Appleton-Century Company, Incorporated, 1941. Sold only as a set (5 vol. — \$50.00).

These two volumes complete the set, and a general index is supplied to all five volumes. Each section has been written by a man particularly interested in the system of the body under discussion. Volume IV deals with the diseases of the gastrointestinal tract, the genitourinary organs, the kidneys, the blood and the locomotor system. Volume V is concerned with diseases of the nervous system, metabolism, endocrine glands and skin, with chapters on the vitamins, allergy and chemotherapy, with sulfonamide drugs. The authors are outstanding in their respective fields, and the volumes are thoroughly sound and up to date.

The whole set can be highly recommended, for it maintains a standard rarely equaled in books of this type. Great credit should be given to the expert editing of Dr. George Blumer and his associate, Dr. Albert J. Sullivan.

*Biological Symposia: A series of volumes devoted to current symposia in the field of biology.* Edited by Jaques Cattell, Ph.D. Vol. III. *Muscle.* Edited by Wallace O. Fenn, Ph.D. 8°, cloth, 370 pp., with 15 tables and 82 figures. Lancaster, Pennsylvania: The Jaques Cattell Press, 1941. \$3.50.

The editor of this interesting volume points out that care has been taken to include an aspect of muscle physiology that has gone out of fashion in this country and has been almost totally neglected until recently. However, the rapid progress in this field in recent years justifies the hope that a reasonably complete understanding of the actual mechanism of muscle contraction is not beyond reach. The contributing authors and their topics are as follows: "Introduction to Muscle Physiology," by Wallace O. Fenn; "Muscle Function as Studied in Single Muscle Fibers," by Robert W. Ramsay and Sibyl F. Street; "Muscle and the Heart's Motto," by Frederick H. Pratt; "Muscle Excitability," by Henry A. Blair; "Action Potentials and Conduction of Excitation in Muscle," by Elil Bozler, with a discussion by A. S. Gilson, Jr.; "Conduction in Smooth Muscles," by Arturo Rosenblueth; "The Local Activity around the Skeletal Neuromuscular Junctions Produced by Nerve Impulses," by T. P. Feng; "Action Potentials of Skeletal Muscle," by Allan C. Young; "The Regulation of Energy Exchange

in Contracting Muscle," by Dugald E. S. Brown; "The Action of Muscles in the Body," by Herbert Eftman; "Changes during Muscle Contraction as Related to the Crystalline Pattern," by Ernst Fischer, with a discussion by Francis O. Schmitt; "The Significance of Oxidations for Muscular Contraction," by Otto Meyerhof; "The Efferent Innervation of Muscle," by C. A. G. Wiersma; "On the Nature of Certain Diseases of the Voluntary Muscles," by G. D. Gammon, R. L. Masland and A. M. Harvey; "Theories of Electrolyte Equilibrium in Muscle," by Robert B. Dean; "Electric Potential Changes Accompanying Neuromuscular Transmission," by J. C. Eccles, B. Katz and S. W. Kuffler. All these chapters make interesting as well as provocative reading, and no doubt every library will wish to have a copy of this volume on its shelf for reference by students and investigators in this field.

*Occupational Diseases: Diagnosis, medicolegal aspects and treatment.* By Rutherford T. Johnstone, M.D. 8°, cloth, 558 pp., with 132 illustrations and 26 tables. Philadelphia: W. B. Saunders Company, 1941. \$7.50.

This volume furnishes, in a compact form, information regarding occupational diseases. The author states that his fundamental aim is to outline a basis for the diagnosis and treatment of the commoner occupational diseases, to interpret the medical and legal phase, and to predict, from experience, the expected disability. A considerable amount of space is allocated to workmen's compensation laws in the various states and to the function of the physician as related to such compensations.

Chapters are devoted to each of the common diseases met with in industry. They are condensed to furnish valuable information, so that it is unnecessary to read a more voluminous treatise. A considerable number of case histories are given to illustrate the various diseases. The bibliography is extensive, and the book is well illustrated.

This book should be of particular value to the general practitioner.

*The Art and Science of Nutrition: A textbook on the theory and application of nutrition.* By Estelle E. Hawley, Ph.D.; and Grace Carden, B.S. 8°, cloth, 619 pp., with 140 illustrations. St. Louis: The C. V. Mosby Company, 1941. \$3.50.

The problems of nutrition are always of first importance. And if, in wartime, they are not of enhanced significance, at least they are more difficult of practical solution. What with increased food costs, rationing and, perhaps, difficulties in distribution, nutritionists are likely to find it hard to maintain adequate standards.

Sound books on nutrition will therefore be — as they should — studied with particular care. And this is a sound book. It discusses the general nutritional requirements of the body; the various food elements, qualitatively and quantitatively, that must go to maintain them; food requirements under special conditions; the diet therapy of various diseases; and lastly (in a section of more than a hundred pages), the choice, preparation and serving of foods.

It is, as most such books are, designed rather for reference than for continuous reading, and its value is enhanced by numerous charts, tables and recipes. Its weakest feature is its pictures, some of which are poorly reproduced and others seem to be of slight importance, if not actually superfluous.

## MENTAL DISORDERS ASSOCIATED WITH PREGNANCY AND THE PUERPERIUM\*

MABEL D. ORDWAY, M.D.,† AND ANNETTE M. MCINTIRE, M.D.†

BOSTON

IN an attempt to determine the existence of a psychosis due to etiologic factors found only during pregnancy, labor and the post partum period, many valuable and interesting reports of cases have been published. In 1847, James MacDonald<sup>1</sup> made a comprehensive study of puerperal insanity at Bloomingdale Hospital (now New York Hospital, Westchester Division). He included the mental disorders occurring during pregnancy, parturition and lactation, and classified his 66 cases diagnostically as mania, monomania and dementia.

C. F. MacDonald,<sup>2</sup> in 1899, recognized three distinct types of insanity occurring during the puerperal period, namely, puerperal mania, puerperal melancholia and puerperal dementia—the last, however, being rare as a primary affection.

Jones,<sup>3</sup> in an article on puerperal insanity published in 1903, used a more modern classification of these mental disorders

(1) that which occurs during pregnancy, (2) that from the date of parturition to six weeks after confinement, which we shall refer to technically as puerperal insanity, (3) insanity occurring during lactation and dating from six weeks after confinement. This classification is more convenient than accurate. Insanity is and ever will be, the product of two factors, stress and heredity.

Kilpatrick and Tiebout,<sup>4</sup> in a study of 72 cases admitted to Bloomingdale Hospital in the years 1911-1923, found that diagnostically their cases fitted under four major headings: delirium, manic-depressive psychosis, schizophrenia and psychoneurosis. As a result of this study, they concluded that childbearing apparently presents many problems of a physical and psychical nature that play a definite role in the production of psychoses. These problems of themselves, however, do not

determine the type of reaction but merely serve as exciting or precipitating agents in the onset of the illness.

In 1926, Strecker and Ebaugh<sup>5</sup> presented an article on psychoses occurring during the puerperium. In their study of 50 patients, the diagnoses reported were manic-depressive psychosis (18 cases), toxic-exhaustive psychosis (17 cases), dementia praecox (13 cases), paresis (1 case) and psychoneurosis with psychotic symptoms (1 case).

Saunders,<sup>6</sup> in 1929, reported observation on 75 women admitted to the Sheppard and Enoch Pratt Hospital who developed mental illness coincident to childbirth. This study included only of psychosis before the end of the first month after those patients who gave a history of symptoms delivery. The belief was expressed that a psychosis in the puerperal period may be an isolated experience in the life of a woman; on the other hand, there may be repeated attacks of mental illness with other children, or there may be psychoses at other times.

In 1937, Karnosh and Hope,<sup>7</sup> in their study of 231 cases selected from the records of several hospitals, concluded that the stormiest psychoses associated with childbearing develop in the period immediately after delivery, and that the only consistent or characteristic element in true post-partum psychosis is delirium, which appears in varying intensity.

Smalldon,<sup>8</sup> in 1940, in a careful study of 220 cases admitted to the New York Hospital, Westchester Division, in the years 1922-1938, gives a brief review of the changing opinion of the medical profession regarding the psychotic reaction associated with pregnancy and childbirth. He found that only about 36 per cent in the series were classified as deliriums directly attributed to the toxic-exhaustive factors of reproduction. The majority of the patients were found to have manic-depressive psychoses, the depressive type predominating. A lesser number were cases of dementia.

praecox, chiefly of the catatonic and paranoid types. Twenty-eight patients had psychoneuroses, and only 8 of the 220 cases were diagnosed as toxic-exhaustive psychoses. Smalldon emphasizes the difficulty of generalizing regarding the mechanisms of the reactions found in post-partum psychoses. He calls attention to a universally recognized dictum among psychiatrists that "each case of a series of post-partum illnesses must be considered as an individual, non-generalizable problem."

Linn,<sup>9</sup> in a recent study, endeavors to justify the use of the term "postpartum psychosis" as a clinical entity. He obtained his figures from several large centers as shown in his valuable contribution to the literature on this subject.

The mental disorders associated with pregnancy and childbirth appear to have little influence on maternal mortality, as shown by a study conducted by the Obstetrical Society of Boston and the Boston Department of Health.<sup>10</sup> No reference to mental disorders is found in this report.

DeLee,<sup>11</sup> who states that psychoses may begin during pregnancy or may be aggravated by it, observes that a bad heredity is found in half the cases of psychoses occurring during pregnancy and the puerperium. He also states that disturbed metabolism is commoner in women whose nervous systems are not equal to the strain of pregnancy and that, without doubt, the strain of labor is too much for many nervous systems. He believes that prolonged painful labor, without infection, explains many cases of puerperal insanity.

Some observers consider the beginning of involution of the reproductive organs and the early part of the process of lactation to have a distinct bearing on the development of puerperal psychoses.

These studies show that until about 1900 most of the textbooks on the subject made a distinction between mental disorders associated with the puerperium and those occurring apart from childbirth. For the last thirty years or more, the trend has been away from the belief that a specific psychosis occurs in the pregnant and post-partum states. The consensus among most psychiatrists is that etiologically the problems of pregnancy and childbirth do not determine any given type of psychosis.

If studies of these puerperal psychoses have little true scientific value, they do make a distinct contribution to the individual psychiatrist, the general practitioner and the specialist in obstetrics. It is to these members of the medical profession that the laity turn for advice concerning childbearing.

With increasing frequency, local physicians ask whether a woman who has had a mental breakdown following the birth of a child should be

advised against further childbearing. These, as well as other pertinent questions relating to psychoses occurring during the childbearing period, stimulated a review, and a further analysis, of the cases admitted to Glenside Hospital. In addition to the results of our own observations, we have, as noted above, turned to the published reports of other observers for additional data.

The individual patient who has recovered from a psychosis occurring post partum is deeply concerned about possible future pregnancies. Her husband is also anxious to know whether further childbearing should be avoided. They sincerely wish to avoid future mental attacks for the patient, and they wish to know the hereditary dangers for their children. They want the truth. Unfortunately, it is not possible to give a positive assurance of freedom from future mental breakdown to any inquirer.

The literature on this subject indicates that a woman who has recovered from a post-partum psychosis or a severe psychoneurosis occurring for the first time during her first pregnancy may perhaps safely become pregnant again. As in other mental disorders not associated with childbearing, the constitutional predisposition of the patient, the personality make-up and the precipitating factors are of great consequence to the physician who attempts to give even a tentative prognosis. Physicians generally regard pregnancy and childbirth as rather simple primitive biologic phenomena. According to statistics, the majority of women who bear children suffer very few complications incident to childbirth. It is rather loosely stated that only 1 in 700 to 1200 women reacts by a psychosis during pregnancy or following childbirth.

The present report is based on a study of a group of 45 patients admitted to Glenside Hospital; 43 entered during a twelve-year period, 1930-1941, inclusive; 23 patients were twenty to thirty years old, and 20 were from thirty to forty years of age when the psychosis occurred. One patient was a forty-one-year-old primipara, and another, a multipara, was forty-three years old at the time of her psychosis. The case records show that there were 27 primiparas, including a patient who was six or seven months pregnant when she was admitted to the hospital.

In the group of primiparas, 17 patients were under thirty years of age, 7 were between thirty and thirty-five, 1 was thirty-six, 1 was thirty-seven, and one was forty-one years of age. The family histories in 16 cases were said to have been negative for nervous and mental diseases; the other 3 patients had histories of manic-depressive psychosis before marriage. Of these, 1 patient had a psychotic heredity, 1 had an unstable family environ-

ment, with a definitely alcoholic sibling, and 1 had an irrelevant family history

In the multiparous group of 18 patients, the youngest was twenty three years of age, and the oldest was forty three. Only 1 patient in this group gave a history of a previous psychosis. The family history in 12 cases was negative for nervous and mental diseases.

Religion did not seem to have any particular bearing in the development of mental disorders in this group: there were 17 Protestants, 15 Roman Catholics, 10 Jewesses and 1 Greek Orthodox. In 2 cases, the religion was not stated.

Twenty seven of all the patients were reported as being mentally and physically well during pregnancy. Eighteen were emotionally upset for various reasons, such as fear and apprehension, irritability and nervousness, mental conflict about premarital pregnancy, hypochondria and poor adjustment to environmental conditions. 2 patients were mildly depressed, 1 was mentally overactive, 1 had had two babies in eighteen months, and 2 definitely did not want a baby and attempted abortion. In 1 case, the patient was worried because her husband did not want a baby. Two multiparous patients became psychotic following induced abortions (in both cases, infection followed the abortion). One of these women had experienced three normal pregnancies and believed that she and her husband could not afford a fourth child. The other had one child and could not afford to have another because her husband's earnings were very small. The former became mildly upset emotionally only in the last month of pregnancy, and the latter became depressed early.

No history or other evidence of alcoholism was found in this group. Narcotics and analgesics used preceding and during labor seemed to have no significant bearing on the development of the psychosis.

The stress of present-day life did not seem to be greater in this group than in the average American family. In several of our cases, worry over finances was given as a contributing factor to the mental breakdown. Since the majority of these patients were admitted to a hospital for nervous and mental diseases for the first time during the twelve years subsequent to the great financial crash of 1929, comparisons between this period and the preceding twelve years cannot be drawn. Worry over financial circumstances and excess of physical labor during pregnancy have doubtless always had a deleterious effect on the health of many women. Eighteen patients were considered emotionally unstable before marriage. There were no unmarried mothers, although in 2 cases pregnancy occurred

before marriage. In 7 patients, there was a definite psychopathic heredity.

Intelligence was found to be good in the majority of this group, and several patients were of superior intelligence. Thirty nine patients were

tions. The following case reports are brief abstracts from the records of patients who developed more or less serious mental symptoms.

#### CASE REPORTS

**CASE 3 Toxic-exhaustive psychosis.** A 25-year-old multipara had an irrelevant family history. Her previous physical health had been good. She was described as a pleasant child, normal emotional life, not easily led, a calm reserved young woman who enjoyed fine things. She graduated from high school at the age of 17, worked as a saleswoman for a few years and then married. Her first pregnancy resulted in premature delivery at 6½ months. Her second pregnancy resulted in the birth of a premature infant weighing 1½ pounds. When told of its death a few days later, she became emotionally upset and claimed that she could see her baby. Removed from the hospital to her home on the 10th day, she rapidly developed somatic complaints, suffered from insomnia and was somewhat violent. There were visual hallucinations, feelings of unreality, many somatic complaints and periods of confusion. At the time of admission to Glenside Hospital there was a pronounced secondary anemia. Although there was some improvement in her condition the patient was taken home against medical advice after about 5 weeks of hospital care. There was no evidence of syphilitic infection to account for her inability to carry her babies to full term. The patient was readmitted to this hospital

a few years later suffering from insomnia, and it was believed that she was hallucinated. According to her husband, she had made a good recovery from her previous psychosis within a few weeks and then seemed quite normal. But she constantly looked forward to having children and brooded a good deal over her deceased infant. She was again taken to her home against medical advice at the end of 5 weeks. The second psychosis in this case was diagnosed as a catatonic type of schizophrenia.

**CASE 4. Manic-depressive psychosis: manic type.** A 27-year-old primipara with a definitely psychotic heredity and an intelligence above average, at the age of 17 had a manic-depressive psychosis, manic type. On recovery from this illness, she entered a normal school, graduated, and taught school. She was married at 22. Except for the poor heredity and the fact that a psychosis developed about 10 days post partum, her "nervousness and irritability" shown at times throughout her pregnancy would not have been notable. She went through a fairly typical manic episode, which lasted for about 3 months.

**CASE 5. Manic-depressive psychosis: depressive type.** A 39-year-old, well-educated multipara had had no previous mental attacks. The family history was irrelevant. Her last child was born  $3\frac{1}{2}$  months before she was admitted to Glenside Hospital. Physical examination revealed a lacerated cervix; otherwise, the general physical condition was good. This patient was "much depressed before, during and subsequent to confinement." Catamenia had returned before we saw her, and "were too frequent, too profuse, and of too long duration during her hospitalization of 4 months and 10 days." There were some delusions of a mild paranoid type. Mental improvement is recorded as "gradual and uninterrupted."

**CASE 10. Psychoneurosis.** This patient was 35 years old when she married the man by whom she had become pregnant. Her anxiety state dated from the time she was certain of her pregnancy. She had always been reluctant to marry because she had an excellent position and enjoyed working. She was described as gay, sociable, high strung and self willed. She enjoyed dancing, and had many friends. There was a strong mother attachment. She got along very well during the first 3 months of pregnancy, and then became depressed and agitated, brooded over having a child, and was fearful. No psychotic symptoms were present during the 30 days the patient was at Glenside Hospital. Improvement was gradual. She gained some insight and became interested, alert and cheerful.

**CASE 17. Toxic-exhaustive psychosis.** A 25-year-old primipara had been married 18 months when her baby was born. Her marital life was "congenial and happy." Her previous health had been good. She was temperamentally cheerful and lively. The family history was irrelevant. During her pregnancy, the patient was "wonderfully well." She was delivered at a hospital. There were no complications. She remained in the hospital for 10 days, did not sleep well, became apprehensive, and heard comments that disturbed her. The patient was transferred to a hospital for mental diseases for a period of observation. On the 20th day post partum, she was admitted to Glenside Hospital. She was confused, disoriented, overtalkative and destructive but not assaultive; there developed a feeling of unreality about her husband and her mother. Later, the patient admitted vague auditory hallucinations. The blood pressure, temperature and laboratory findings remained normal. She was hospitalized for  $4\frac{1}{2}$  months and made a good recovery.

**CASE 19. Psychoneurosis.** A 35-year-old multipara, predisposed to emotional upsets, had had hysterical episodes brought on by frustration 7 years previously. She had always had difficulty in adjusting herself to environmental changes. There was a history of asthmatic attacks for many years. Her mother was psychotic. The patient was said to be very industrious, with an intelligence above the average. She was married when 25 years old. Her first child was 10 and the second (an unwanted baby) was 1 year old. The patient "had not been well since the beginning of her last pregnancy." She was discouraged because she had not thought she would become pregnant again. She tried to abort, without success. After the baby came, she was restless and nervous, her asthma grew worse, she was depressed and tearful, shunned social contacts, "felt nervous" and tried to run away. She remained at Glenside Hospital 30 days and seemed to respond favorably to psychotherapeutic treatment. She was not well enough to go home, but left the hospital against advice.

**CASE 22. Manic-depressive psychosis: depressive type.** A 46-year-old multipara was admitted to Glenside Hospital suffering with a manic-depressive psychosis. This was her second attack. Her case is recorded here because during her first pregnancy she was "overactive and flighty." This mental state continued until after the death of her baby, when it was 7 months old. Two months later, her mother died, and the patient went into a depressed state that lasted several months. There were two subsequent pregnancies, with delivery at term without incident. The family history was negative so far as known to the informants.

**CASE 26. Toxic-exhaustive psychosis.** A 29-year-old primipara whose previous health had been "good" had been married about a year. One sibling had been a patient at a hospital for mental diseases. Previous to delivery, physical examination revealed a loud, blowing systolic murmur, apparently of rheumatic origin. The patient developed mental symptoms soon after childbirth, and was admitted to Glenside Hospital when her baby was 2 weeks old. At first, she was fearful of insanity. At times, she had both auditory and visual hallucinations. Later, she was confused, disoriented, extremely agitated, excited, fearful, suicidal and homicidal. She developed local abscesses and ran a septic temperature for several weeks. At the end of a month, improvement began and was progressive and continuous until she went home "on visit." The duration of the psychosis was 3 months.

## DISCUSSION

Emotional instability is commonly found in women during the period of pregnancy. It is not, however, necessarily caused by this state. Many of our patients, and members of their families as well, assured us that their general health during this period seemed to be better than at other times. It is highly improbable that pregnancy in itself, in a previously healthy woman, may be considered a true etiologic factor in the psychoses of pregnancy and the puerperium.

It is true that sociologic and economic factors complicate the clinical picture of pregnancy and childbirth. Inherited (constitutional) tendencies and the personality make-up of the patient are

important contributory conditions. No two persons react in the same way to the ordinary stresses of life, and individual personality trends and problems may act as predisposing factors in any mental breakdown. It is essential to study the patient as a person quite apart from her specific symptoms. Marriage calls for adaptation to a new experience. Childbearing makes more new demands on the woman, and these demands often come before she has successfully adapted herself to the personality of her husband and to the new environment confronting both of them. Maladaptation usually indicates considerable emotional conflict, which alone may produce a so-called "nervous breakdown." Feelings of guilt often result from the use of contraceptive measures, and such feelings may be of serious import when abortions have been induced or attempted, or in an extremely psychoneurotic woman.

This series of 45 cases indicates that as contributing or precipitating factors pregnancy and labor play a significant part in the psychosis occurring within three weeks after delivery and also in many cases in which the psychosis develops somewhat later. Only 2 patients in this series became psychotic as late as four months after delivery.

So far as symptomatology and prognosis are concerned, the fundamental symptoms manifested in the psychoses under consideration do not seem to differ from those of the other biogenic psychoses. Pregnancy and parturition are emotional as well as physical experiences. In an article bearing on experience as a psychiatric concept, Kahn and Cohen<sup>12</sup> state:

Every individual has a *capacity to experience* which is peculiar to him. That many individuals share similar experiences is quite possible; that all individuals have the same experiences is impossible. For, each individual brings into the world *his* capacity to experience, and each individual differs from every other individual in that all his capacities, necessarily including his capacity to experience, have been derived fundamentally from the biological potentialities which he has inherited from his progenitors.

We feel justified on the basis of experience in accepting the fairly well-demonstrated postulate that individual biogenic weakness, although the resistance to environmental conditions may be only temporarily lowered, underlies all the biogenic psychoses. This study does not show that toxic-exhaustive factors, which are apparently the result of pregnancy and childbirth, produce symptoms that are different from those accompanying other toxic-exhaustive psychoses. Psychologic stresses, and the varying reactions of the patient

to them, are of the same relative importance here as in the other biogenic and psychogenic psychoses. In many other types of mental disorder occurring in adult life, one may find a history of long-continued economic stress given as a contributing cause. And unquestionably this type of strain in itself produces a profound anxiety state in the woman who is about to bring a child into the world. Other situational factors—such as incompatibility between husband and wife, an undesired pregnancy, a definitely unwanted child, a feeling of inadequacy about assuming the responsibilities of motherhood, and a previously sheltered life without having achieved emancipation from her own protective mother or father—are noted as contributing factors. One or more of these conditions recurred often in the 45 cases here considered.

### CONCLUSIONS

Mental disorders associated with pregnancy and the puerperium as reported by many observers may easily fall under the usual familiar nosologic headings. Many observers have found nothing specific in psychoses occurring post partum. However, as contributing and often as precipitating factors, these two incidents in a woman's life should not be disregarded.

The term "puerperal insanity" will doubtless fall into disuse, and a better term will be substituted. At present, it seems to be commonly used only in a descriptive sense.

Owing to emotional and functional alterations during pregnancy and the puerperium, many women are, by reason of poor heredity, unable to go through the long period of gestation without a break in mental and emotional integrity during the puerperium.

Endocrine and metabolic imbalances may play a large part in these and other psychoses. Evidence of their etiologic significance is insufficient for any more definite statement to be recorded.

The great need for early educational preparation for parenthood for both sexes cannot be too often emphasized, or too often stated in nonmedical as well as medical literature.

Prenatal care, including, when indicated, psychiatric study and psychotherapy of a re-educational character, should be readily available to every pregnant woman, no matter what her social and economic status.

## PRESIDENTIAL ADDRESS\*

CHARLES H. DOLLOFF, M.D.†

CONCORD, NEW HAMPSHIRE

**I** VIEW my task this evening as definite and inescapable. I must give a presidential address, saying words and expressing thoughts befitting a time-honored anniversary, yet finding myself without the wisdom and special ability the occasion calls for. Not of the same mold as most of you, with an experience and training of quite another sort, I have from my medical cradle been nurtured in a cloistered life that scarcely fits me for a real understanding of the things that are of interest and concern to you in the private practice of medicine, and I frankly confess to being considerably confused and uncertain of the form and substance this address should take.

Had I followed the example of my illustrious predecessor (and, whom better could one pattern after?), I would, without more ado, have prepared a paper for the afternoon session. But since a president's paper, being *ex cathedra*, is not open to discussion or even question as to its validity or scientific integrity, I hesitated. Ez Jones, of course, would have no need for any such hesitation.

Therefore, it has seemed best to say whatever I have to say, here at this banquet where the warmth and encouragement in these many feminine eyes will serve to dilute and weaken what otherwise would have been just the concentrated essence of a cold stare from a roomful of scientifically critical conferees.

Had I elected to read a paper this afternoon, being mindful of the old admonition that "the shoemaker should stick to his last," I believe I would have said something about that very much misunderstood and therefore quite unhappy branch of medicine known as psychiatry. And, mark you, at the very onset I would have boldly insisted that psychiatry must now be recognized as an important aspect of general medicine, as well as a weird specialty, in spite of the woman who said to one of my kind, "If you were only a physician instead

of a psychiatrist I should like you to take my husband's blood pressure," and in spite of the man who commiseratively said to me, "Now if you were only one of them M.D.'s you could probably get some new tires."

Psychiatry is an aspect of general medicine because mental and emotional factors play such a significant role in invalidism. More and more are we being oriented to the concept that there is a definite relation between physical and mental disorders. More and more is the value of treating the total personality, the patient as well as his disease, being better appreciated.

Thus, the true function of medicine must be the study and treatment of man, himself, as well as his organs and cells, if the practice of medicine is to be kept very much above the level of a glorified veterinary science, and I dare say even a horse doctor would admit that if he could only tell what was on the horse's mind he could the better treat the horse's belly.

From the practical standpoint of treatment, however, it is still quite useful to consider the individual not as one person but as two,—a physical man and a mental man,—the treatment required varying according to which man it is, provided, of course, we bear in mind that it may be both.

Therefore, in our conquest of disease we should, to use a modern idea, wage a total war. Yet how can physicians wage total war when lawyers get so much in the way? How can we wage total war against pathologic drunkenness, for example, when the legal dictum is that a man may drink himself into the grave and his family into destitution unless he can be certified as "insane," generally a difficult thing to do because incompetency, the legal test, is rarely manifest? And how can we wage total war against mental disease in general when the law hinders early treatment by making certification necessary for admission to a remedial hospital, branding the mild or recent case with the word "insane," with all the unfortunate consequences that flow therefrom? Lawyers are naturally concerned with arranging for the protection

\*Presented at the annual meeting of the New Hampshire Medical Society, Manchester, May 13, 1942.

†Superintendent, New Hampshire State Hospital, Concord.

around which there still rages much controversy but whatever one's opinion about the Freudian theories and technic, it must now be conceded that from being static, psychiatry has become dynamic, from being chiefly descriptive, it has now become interpretive, and from treatment en masse, it is now recognized that each patient is an exquisitely individual problem.

In this war that engulfs us, there is more need than ever before for psychiatry's contribution. Those mentally unfitted for army service must be eliminated. Civilian morale must be maintained. So loosely, so ambiguously, has the term "morale" been used that it has almost lost its meaning. Real morale is built neither by slogans, catch phrases, song and dance acts nor even by movie actresses on whirlwind visits through army camps. At best, this is only diversion and has little to do with basic principles. If you would know morale, observe the Russian people and the Russian army. Obviously, they are a people who believe very deeply in the things for which they are fighting. It is their faith in themselves and their institutions that is sustaining them. There are no slogans, dances or even hostesses in the Russian camps. May we too learn how to sustain ourselves through the weariness of continuing frustration! There is work, sacrifice and responsibility for everyone. Not a vestige of the world we have dimly anticipated for those who follow will continue if we fail each other.

I spoke in the beginning of my feelings of inadequacy for meeting the challenge of this occasion, but it is clear to me now that it should not be difficult to pay tribute to the strength and harmony of this venerable society.

One of my duties this year was to send a letter of felicitation to the Connecticut Medical Society on the celebration of its sesquicentennial. I wrote:

The New Hampshire Medical Society congratulates the Connecticut State Medical Society on the approaching one hundred and fiftieth anniversary of its founding. We recall the pleasurable satisfaction we experienced at our sesquicentennial way back in 1941. Connecticut did well to emulate New Hampshire a century and a half ago in forming a state medical society and in profiting from the longer experience of the older brother in the right way to maintain the vitality necessary for a long life. If you again emulate New Hampshire in the form of celebration you deem worthy of such a notable event, you will make it a festival such as will give your founding fathers at least one very restless night.

I tell you this because in the first place you are entitled to know what kind of rascally advice your president gave to our neighbor, and secondly because it is pleasant to recall and relive for the moment the very happy celebration of a year ago. To be sure, it was quite a let-down for an august and dignified society such as ours, but very helpful and mentally healthful, if indulged in only once in a hundred years, more or less.

One hundred and fifty years is indeed a long life, and there must have been some need in the hearts and minds of the members of this society to explain its prolonged virility through many social and economic stresses.

The most valuable purpose of such an organization as ours is the improvement of its members by advance in knowledge. No class stands in greater need of getting together frequently. You are called on to decide complicated problems involving the well-being, the very lives, of your fellows. The experience and knowledge of even the most learned is limited, and it is easy to become rusty. There is no corrective equal to discussion with others.

To be sure, much of what has been said here during the past two days will be published in the *Transactions*, but the man deceives himself who fancies he can derive the same benefit from reading the transactions as he would from attending the meetings, for he misses the second great object to be obtained in a society like this—the binding of its members together by friendly association and personal acquaintance. More than ever, in these dark and tragic days, do we need the trust and friendship of each other.

I still view with astonishment my election to this presidency. I was deeply touched by the honor and shall always think of it as an index of your democracy.

However, beyond this one election, I do not see that your habits are much akin to those of our great American democracy, for although fate has made me a war president, it does not escape my observation that you have no apprehension about "swapping horses while crossing a stream." I salute the new horse and assure him the load is not heavy. There are draft horses to do the work.

Finally, in surrendering the gavel, I can at the moment think of only one thing nicer than being your president and that is being welcomed into that charming coterie of aging men—your ex-presidents.

# THE NEUROLOGIC ASPECTS OF DEFECTS IN SPEECH AND READING

EDWIN M. COLE, M.D.\*

BOSTON

MUCH of man's success depends on the use of words. There is surprisingly little interest on the part of the medical profession in how people use words. Some time ago, I thought it would be of value to establish a clinic to study patients and their use of language. "Language" has many connotations, and perhaps a better term would be "wording," which means how words are produced in spoken and written form, and how they are received by ear and eye. This study has been the function of the Language Clinic at the Massachusetts General Hospital.

Of the patients who come to the clinic for study, the youngest group and one of the largest groups is that of children of three and a half, four and five years of age who do not talk or do not talk in an understandable way. These children usually appear two or three weeks before the opening of school, when worried mothers bring them in saying, "Johnny doesn't talk yet, and he'll have to learn before Labor Day when he goes to school." Or else the worried parent who has waited still longer brings the child in during October with the sad tale that the child has been rejected from school because he could not talk or because his speech was not understandable. Sometimes, parents are worried earlier, and the children are seen before they are ready for school. Such parents are usually apprehensive about the child's intelligence, for intelligence and ability in wording are synonymous to many. This, of course, is not true.

In the study of this group of poor talkers, the late talkers and poor talkers can be divided into several groups. In the first place, there are some who do not talk apparently because of poor intelligence. Such a patient, a little boy of seven, was brought to the hospital recently. He had for the second time been rejected from the first grade because his speech could not be understood and also because he could not fit into the group situation at school. The teacher thought that his lack of development in talking made it impossible for him to fit in with the other children. So far as could be ascertained, the child had no physical defects as judged by an examination of his sensory-motor system and his general health. He had had but little illness. His speech was quite difficult to understand. He used many words that could be understood only by his mother, who was adept

at interpreting them. A careful psychometric examination was made, nonlinguistic tests being used, and the child's mental age was found to be far below his chronologic age; in fact, it was only a little above three years of age. In such a case, then, in the absence of other causative factors, it is fair to say that poor intelligence, as measured by suitable intelligence tests, is the cause of poor wording. This is not always so, for children with very low mental ages sometimes manage to talk quite well.

Another subgroup of late and poor talkers includes children with deficient hearing. These children are puzzling, for they hear some sounds, and hence the fact that they are partially deaf escapes many observers, including their parents. They may like to listen to the radio, and they may jump when a dog barks or a bell rings, so that obviously they are not deaf. As a matter of fact, they often respond to commands, and the mother quite rightly says that they understand what is said and, therefore, they must have hearing. Careful evaluation of these cases, however, may show that a good deal of hearing has been lost. Some of these children have a loss of hearing in the high frequency range. This is a selective type of deafness, excluding many of the consonant sounds, such as *s*, *sh*, *t*, *th*, *f*, *v* and a few others, from the child's hearing. Such children are unable to reproduce the speech that they do not hear. Their speech is quite unintelligible, for it is without so many of the sounds one is accustomed to hear. Some of these patients have a selective or high-frequency type of deafness; others are slightly deaf in all ranges of frequency. There are a good many such cases; certainly, there are enough to make one realize the advantage of having a painstaking evaluation of a child's hearing done by a competent otologist before any other therapy is begun. Hearing aids in these cases may be of great assistance, and other measures may improve the child's speech.

There is a third subgroup of nontalking children. This, in my experience, is a small one. It consists of children who seem to hear sounds but do not associate meaning with words. They have been described in the literature as "word deaf." Such children obviously do not respond to their parents' words, and are usually very much interested in movements, expression of faces and all the other meaningful signs they can observe.

\*At present in leave of absence from Harvard Medical School. Head of the Linguistic Clinic and assistant in neurology, Massachusetts General Hospital.

Most children, however, who do not talk well or do not talk at all at the expected ages seem to have no physical or mental defects; that is, their intelligence is average or better, their hearing is adequate, they show no physical defect of the organs of speech, and there is no evidence of brain or nervous-system disease. Yet they talk late, or, when they talk, use poor speech, which may be described as very marked baby talk. This group, which is large and in which there is no demonstrable defect, is a particularly challenging one, which I wish to call "motor speech delay."

Second to these children who do not talk well at the proper time come the group who talk with a stutter. I use the terms "stuttering" and "stammering" interchangeably, for there is no difference in the underlying processes. Some persons have difficulty because of repeating one sound over and over again; others, who cannot get a single sound out, have what is known as a "block type" of stutter. These disturbances may be so severe as to be tremendous handicaps, or they may be so slight as to escape observation. The hemming and hawing of many speakers is a form of this same thing. One usually sees little children about to start school, or who have just started school, who stutter. Their parents quite rightly feel that the handicap may be disturbing to school progress, and hence the patients are brought in for help. Frequently, the stutterer is an adolescent whose career in school has been a difficult one because of his speech defect. At adolescence, he wishes to develop a more useful personality and, to this end, to eradicate his speech defect. Stutterers who present themselves for help consequently range in age from early childhood through the growing years. One can find among them only one common denominator—the fact that they stutter. Their organs of speech and neurologic control vary as among other persons; there is no commonly found physical defect to explain the stuttering. Stutterers, then, are a group gathered together because of their symptom.

There are, of course, large numbers of children who come in to the Language Clinic because of organic defects interfering with speaking. In enumerating such defects, faulty alignment of the teeth should be mentioned first. I hasten to add that it is surprising how well children can talk with very poorly aligned teeth, and it is only rarely that the teeth are the cause of poor speech. Cleft palate is another organic defect conditioning speech. The operative repair of cleft palate is now so well performed that it is a pity that more patients do not talk better after the operation. That they do not, in my opinion, is because of inadequate postoperative training. If a child is given an altered equipment for the production of

speech, he must be taught properly how to use it, for he still has in his memory, as correct speech, the sounds so poorly enunciated with his cleft palate. As the operative age becomes lower and lower, this hazard becomes less and less, but even so, the soft palate needs to be stretched and used properly if good speech is to result. Among organic defects influencing speech, deafness should be referred to again. Suffice it to say that many children apparently deaf since very early childhood escape notice until they reach the upper grades in school. Finally, there is the large group of organic defects whose lesion is in the nervous system as a result of cerebral birth injury. Many of these children have poorly co-ordinated movements or spastic movements, all of which are reflected in their speaking. In some of these cases, particularly when there seems to be good intelligence, some improvement in talking can be gained with good speech training.

An interesting group in the clinic might be classified as suffering from misuse of the voice. These are children whose speech is defective because, along the line of their development, they misused their voices for one reason or another. In little children, the misuse sometimes follows tonsillectomy when, owing to a sore throat, the child splints his soft palate for a prolonged period, and then develops the habit of talking with a good deal of hypernasality. His speech sounds almost as though he had a cleft palate, and the defect dates from the time of the tonsillectomy. This defect is the child's response to a painful throat, and can readily be overcome soon after the operation by proper throat exercises before the restriction of voice becomes fixed. At puberty, not infrequently, boys misuse their voices and report with a speech disturbance as a result. An example of such a patient was a boy of thirteen, rather small for his age, whose mother brought him in because of his high squeaky voice, which could hardly be heard. He had developed this voice during the six months preceding his hospitalization. On examination, it was found, when he was asked to make certain sounds, that he had a very good, unusually deep bass voice. When questioned about this, the patient rather shamefacedly admitted that he did have this sort of voice but he was embarrassed by it because it seemed so deep and large for a small fellow. He had developed a falsetto speech to save himself embarrassment. Another somewhat similar case is that of a young man of thirty-five who came in with an excessively husky voice. He had been carefully examined in the Throat Clinic, and no abnormality to which the voice could be ascribed had been found. On examination, it was found that this patient had sung in a boys' choir. He had had a very fine soprano voice. During pu-

berty, he continued his work in the choir and found that with some effort he could continue the soprano parts with which he had been so successful. Some time later, he became a singer with a jazz orchestra and was popular because of his lovely, high, crooning voice. It was after using his voice in this way for quite some time that he found it increasingly difficult to speak above a husky whisper. When he was seen in the clinic, he could still raise his voice to a high soprano falsetto tone for singing, but his voice for speaking seemed to have suffered as a consequence.

Another large group of patients seen in the Language Clinic are those who have lost the ability to use language. These are the cases of aphasia not infrequently seen in hospital and general medical practice. Aphasia is by no means limited to aged people who have had shocks, associated with hemiplegia. A good many of these patients are young people who have had vascular accidents or other trauma to the brain and who apparently have years of life ahead of them. A study of aphasia helps one to gain an understanding of the language processes. The patients who lose ability in wording may have a defect chiefly in their ability to say words. Another group of aphasic patients show their greatest defect in ability to read print. They become relatively alexic. Finally, a third group show their greatest defect in ability to understand the spoken word. I do not believe that any one of these parts of the language processes can be affected without causing a defect in the other parts as well. However, the proportion of one defect in relation to the others is a major factor. By evaluating this factor carefully, one learns much that is of great neurologic value regarding the cerebral localization of the lesion causing the aphasia. One also learns that there is an interrelation between the different areas of the brain involved in the language processes. Thus, when the lesion is in the motor speech area in the frontal lobe, talking may be completely lost, where as understanding of words and of print is only partially lost. This interrelation is of particular consequence from the therapeutic point of view. In planning retraining exercises for the patient who is aphasic, one can do much by working through the spheres of language relatively intact, to improve the portion of language most affected. A recognition of this fact also points the way for help in other language problems without recognizing the abnormality. Thus, one can remedy the speech defect by working through the auditory and visual speech areas, that is, through the hearing of words and the reading of print. Similarly, the reading disability is remediable by the backing of poor performance in this one language

process with better performance with the spoken word.

With these facts in mind, it may be readily recognized that no satisfactory work with disorders in wording can be carried on without a thorough study of aphasia. In the sphere of language, as elsewhere in the study of man's biologic processes, knowledge of function is increased by the observation of changes associated with disease.

I have described, then, various groups of patients whose chief difficulty is their output of words. Another large group are examined because of difficulty in school. These children may be regarded as having a learning difficulty. It is self-evident that a child's learning in school is by means of his wording. Facts and school experiences come through his ears as the spoken word, and through his eyes as the printed word. He expresses his thoughts and thereby gains experience, his knowledge being measured by his teachers through more wording, his speech and his written productions. Since wording is the medium by which learning in school is accomplished, learning difficulties frequently resolve themselves into difficulties in wording. The implications of this fact are tremendous and are generally overlooked.

In considering a child's learning difficulty, one of course investigates his general health, which may be a retarding factor, and his physical equipment, particularly his sense organs and his general motor equipment. Further investigation leads to attempts to evaluate the child's intelligence. There are numerous forms of psychometric examinations, all of which evaluate intelligence merely in terms of the given test. Many of these tests are given through the medium of wording, and since many of the children investigated are deficient in this respect, the limitation in language rather than one in intelligence is frequently measured. I know of no test that is foolproof in this respect. Of course, the most unreliable for this purpose are group intelligence tests which require successful use of language before the test can be mastered. Individual intelligence assays, then, must be employed. Even these lean quite heavily on oral directions, and some of them on printed material. Moreover, since they presuppose considerable experience in language, many of these patients, who are deficient in language skill, are at a disadvantage. The most helpful means of evaluating intelligence for this purpose has been to use a fairly large battery of tests, some of which depend almost entirely on performance. When this is done, one usually gains a reliable idea of the child's academic potentialities from the point of view of his intelligence.

One inevitably sees children whose defect is discernible by means of a careful psychometric examination. Such children are described as having a somewhat retarded intelligence, and in some cases this seems to be the explanation of their performance. There are many more, however, who in terms of mental tests have adequate intelligence and whose scholastic achievement is far below what might be expected of them, in view of their chronologic and mental age, and even in view of their grade placement. The so-called, mythical "average child" of eleven years having an average intelligence quotient of 100 should have a mental age corresponding to his chronologic age, and on the basis of average public-school performance, he should be entering the fifth grade in school; theoretically, his performance in arithmetic, reading and spelling, to mention only the fundamental subjects, should be the average for children beginning fifth grade. Of course, such an average child does not exist, and one finds wide variations from this norm. Thus, I have already described the child whose variation seems to be one of retardation in the mental age, accounting for retardation in scholastic achievement and possibly in grade placement. However, some of these children have a mental age that is average or much better than average for their chronologic age, and their performance in school lags well behind what would be expected of their mental age. This inconsistency must be explained. In the absence of physical and mental defects, one must look further for an explanation. When such a child's academic achievement is measured, his performance in arithmetic is generally far superior to his performance in reading and in spelling. When the use of words, printed and written, is concerned, the child's greatest failure is apparent. Here, then, are retarded children whose problem is not so much learning per se as it is the difficulty in wording, particularly in reading, writing and spelling. These cases have been described by others as congenital reading disabilities.

\* \* \*

In this study of cases seen in a clinic devoted to language problems, the difficulty of some patients is explainable on the grounds of organic defect. Others show no organic defects, and yet their wording is defective. Among them, I have described those who acquire the ability to talk late and who talk poorly; one recognizes little children of three, four and five having a motor speech

delay. Then, there are the large group of stutterers, ranging from the very severe stutterers to those whose residual defect is only a slight hesitation in speech. On the auditory side, there are those who do not seem to understand words and hence have difficulty in reproducing them. These are cases of central-type or word deafness. Finally, there are the large group of reading disabilities.

These patients have a common denominator—their heredity. One finds, when investigating the heredity of any one of these types of cases showing difficulty in wording, that in the family there are cases of right-brainedness as well as the usual left-brainedness. By this, I mean a dominant right cerebral hemisphere. The simplest measure, although not always an accurate one, of hemispheric dominance, is the handedness. Thus, a person having right-cerebral-hemisphere dominance is usually left-handed. The dominance for handedness and for language performance is usually, although not always, in the same hemisphere. Of course, right-brainedness does not always occur in a person whose performance in language is defective, but it does occur in his family. Moreover, when one type of hereditary language defect occurs in a family, other types are likely to appear in members of the same family. Thus, in the family of the stutterer, there are cases of late development of speech, as well as reading disabilities and so on. It seems then, that one is dealing with a hereditary syndrome. A possible explanation of this fact lies in what has been learned of the language function by a study of aphasia: the language function is regulated by the dominant hemisphere, the opposite hemisphere having little, if anything, to do with wording. The patients concerned have a combination of opposing dominance. They are those who have inherited a tendency toward a dominant right as well as a dominant left hemisphere. This inheritance sets the stage for poor language performance in any of the respects already described. These children with a poor hereditary setup for language can improve their performance with careful training. To improve performance, it is well to recognize the fundamental lack of ability, for unless one does, methods planned for improvement will miss their point. Furthermore, unless one understands the interrelation between different parts of the language process,—talking, reading and hearing words,—one misses a chief avenue of therapy in the field of language problems.

# SULFATHIAZOLE OINTMENT IN THE TREATMENT OF PYOGENIC DERMATOSES\*

EARL A. GLICKLICH, M.D†

BOSTON

SINCE the advent of sulfanilamide and its derivatives, a beneficial clinical result in many dermatologic diseases has been effected. Beinhauer, Knoll and Perrin<sup>1</sup> observed the response to sulfathiazole, given orally, in 103 patients with sixteen dermatologic diseases. During the course of the oral administration of the drug, many toxic symptoms may arise, such as headache, nausea, fever, burning and itching of the eyes, injection of the scleras and conjunctivas, dermatitis and exquisitely tender and swollen joints, with effusion, leukopenia, hematuria and anuria.<sup>2</sup> Moreover, Spink and Paine<sup>3</sup> treated 16 patients with localized staphylococcal lesions, in 15 of whom the organisms were found in the blood stream. After sterilization of the blood stream by oral sulfathiazole, organisms could still be cultured from the localized lesions. Thus, it seems unwise to subject patients with minor pyogenic dermatoses to the oral administration of the drug, since the toxic manifestations may be severer than the disease and the potential danger of invasion of the blood stream from localized lesions exists even after the blood has been sterilized.

A much simpler method in treating the pyogenic dermatoses is indicated. MacKenna<sup>4</sup> observed that when crushed M and B 693 was dusted on cases of impetigo and ecthyma and covered with zinc paste and a light dressing, the time required to cure the average case was reduced. The same observation with sulfathiazole has been made at the Boston City Hospital since November, 1940. A crude ointment was made by trituration of sulfathiazole tablets and mixing of the powder in a base containing equal parts of lanolin and boric ointment. A more refined ointment was then obtained‡ in which the sulfathiazole was in a suspended state and the size of the particles in suspension approached that of a colloidal one.

Forty-two patients were treated with the crude and refined ointments, with satisfactory results. Twenty had impetigo, 7 pyoderma, 7 eczematoid dermatitis, 1 a recurrent herpes simplex with secondary infection, 1 a herpes zoster with secondary

infection, 3 infantile eczema with secondary infections, 2 disseminated neurodermatitis with secondary infection, and 1 a stasis eczema with secondary infection. Cultures were obtained in 11 of these cases, and the predominant organism was found to be a hemolytic *Staphylococcus aureus* (Table 1).

The patients were instructed to cleanse the involved areas once daily with soap and water, to

fathiazole ointment were compared with those treated with other medications, the results were equivalent or more satisfactory (Table 3).

The following are typical case reports:

CASE REPORTS

CASE 1. W. S., a 17-year-old boy, was admitted to the Boston City Hospital in January, 1941, with impetigo of the face and chin of 1 week's duration. No results were obtained from the use of various local medications. Examination revealed multiple, heavily crusted, oozing lesions on the left side of the face and chin, which were covered

In the 42 patients treated with the crude and refined forms of the sulfathiazole ointment, no local toxic effects were observed. To determine whether absorption of the sulfathiazole took place into the blood stream, 5 gm. of sulfathiazole, in ointment form, was placed on the arms of 4 patients, 2 with normal skin and 2 with generalized erythroderma and secondary infection. The preparation was allowed to remain in place for forty-eight hours by the aid of dressings. During this period, samples of blood were collected at the end

FIGURE 1.  
A shows impetigo of the face on admission to the hospital; B shows the same area after four days' use of 5 per cent sulfathiazole ointment (crude form).

by a yellowish medicament. The patient was instructed to remove the crusts with soap and water and to apply a 5 per cent sulfathiazole ointment (crude form) to the lesions every 2 hours during the day. The patient responded, and was discharged in 4 days with all the lesions healed and with very little evidence on his face of where they had been present (Fig. 1).

CASE 2. T. L., a 22-year-old woman, entered the Out-Patient Department of the Boston City Hospital in March, 1941, with an infectious eczematoid dermatitis involving the pinna and external auditory canal of the left ear of several weeks' duration. Examination showed an oozing, crusting dermatitis, with moderate edema. The patient

of six, nine, twelve, twenty-four and forty-eight hours. At the times when blood was collected, all urine was saved. Sulfathiazole levels were determined on both the blood and urine specimens, and it was found that minute amounts of the drug were absorbed into the blood stream and excreted into the urine. Thus, it was concluded that sulfathiazole in ointment form is less likely to produce the systemic toxic manifestations that one may observe during the administration of the drug orally.

## SUMMARY AND CONCLUSIONS

Forty-two patients with eight different dermatologic diseases, which were caused by pyogenic organisms (mostly hemolytic *Staphylococcus aureus*) per se or were secondarily infected, were treated with an ointment containing sulfathiazole.

The strength of the sulfathiazole made little difference, the infections cleared more quickly, as a rule, than infections treated by other means, no

of the blood stream from localized lesions can occur after discontinuance of the drug orally, and because the use of the drug should be reserved for far more serious illnesses.

# HEMATEMESIS DUE TO RUPTURE OF AN AORTIC ANEURYSM

## Report of a Case

BORIS KAPLAN, M.D.\*

NEW BEDFORD, MASSACHUSETTS

THE history of aneurysm is very old. Galen<sup>1</sup> knew external aneurysm well, and in the second century, Antyllus<sup>1</sup> devised his operation of incising and emptying such a sac, inclosed between ligatures. Internal aneurysm was recognized first by Fernelius<sup>1</sup> in the sixteenth century. Later in the same century, Paré<sup>2</sup> suggested the relation of aneurysm to syphilis. Lancise,<sup>3</sup> in 1728, classified aneurysms, but not in the modern sense. Hunter,<sup>3</sup> in 1757, used the terms "true" and "false" in the modern sense and also described the symptoms of pressure he encountered in 5 cases of aneurysm. Corvisart,<sup>4</sup> in 1812, described various signs and symptoms; he called attention to the thrill, retro-manubrial dullness on percussion and inequality of the pulses. Oliver,<sup>5</sup> in 1878, described the tracheal tug. Thoma,<sup>6</sup> in 1888, wrote concerning the pathology of aneurysms. Döhle,<sup>7</sup> in 1895, discussed the microscopic changes in syphilitic aortitis, and finally Reuter,<sup>8</sup> in 1906, described the *Treponema pallidum* in the wall of the aorta in aortitis, and by so doing established the importance of syphilis as a cause of aneurysm.

The disease occurs more frequently in males than in females, in a ratio of 5:1. It is five times more frequent in Negroes than in Whites. Although aneurysm occurs at all ages, the greatest incidence is between thirty-five and fifty-five. Boyd,<sup>9</sup> in an analysis of 4000 cases of aortic aneurysm, states that post-mortem statistics indicate that aneurysms account for 0.1 to 0.5 per cent of deaths in American cities. According to Kampmeier,<sup>10</sup> the incidence of this condition has decreased by more than half in the past decade.

According to Boyd, the ratio of aneurysm in various portions of the aorta is approximately 10:7:3:1 for the ascending, transverse and descending segments of the aortic arch and the descending thoracic aorta, respectively.

In practically all cases, syphilis is the cause. Arteriosclerosis, tuberculosis, trauma and mycotic infections play a very minor role.

The diagnosis is based on signs and symptoms and x-ray findings. The physical signs of thoracic aneurysm are too well known to require enumeration here. It may be comparatively easy to recognize a classic case of aneurysm after a careful physical examination. However, in many cases,

as in an aneurysm of the upper descending aorta, the process may be so latent and the signs so negligible that recognition may tax the ability of the most experienced clinician. In such cases, the diagnosis is made on suspicion or incidentally on x-ray examination. Osler<sup>11</sup> wrote, "There is no disease more conducive to clinical humility than aneurysm of the aorta."

The following case of aneurysm of the descending segment of the aortic arch is reported because the condition was undiagnosed and because the patient died of an unusual complication—rupture into the esophagus.

### CASE REPORT

A 58-year-old clerk entered St. Luke's Hospital because of hematemesis. For the previous 2 or 3 weeks, the patient had complained of "gas pains" in the epigastrium coming on directly after meals and relieved by saleratus and pills given by his physician. There was no nausea, vomiting, diarrhea, constipation or specific intolerance to fatty or fried food. The patient had been working during these 2 weeks. On the morning of admission, he suddenly felt a general weakness and vomited about a pint of bright-red blood. He was immediately taken to the hospital, where he again brought up a glassful of bright-red blood.

The patient had had pneumonia 1 year previously and an acute upper respiratory infection 2 weeks previously that had since disappeared. He had had no dyspnea, orthopnea, cyanosis or edema. His mother had died of cancer. His wife and a son were well. A daughter died, at the age of 16, of heart trouble.

Physical examination showed a well-developed, fairly well-nourished man who was somewhat pale and extremely apprehensive. The temperature was 96°F., the pulse 78, and the respirations 20. The pupils were round, regular and equal, and reacted to light and accommodation. The scleras were clear. The conjunctivas were moderately pale. The mucous membrane of the mouth was of fair color. The tongue protruded in the midline, without deviation.

There was no stiffness or retraction of the neck. No lymph nodes were palpable. No dullness or rales were present in the lungs. The breath sounds were normal. The heart was not enlarged to percussion, and the sounds were of good quality. The rhythm was regular, with no murmurs. The blood pressure was 80/60. The abdomen showed no spasm or tenderness, and no masses were felt. The extremities were symmetrical, without ulcerations. The knee jerks were normal.

Examination of the blood showed a red-cell count of 2,600,000 with 54 per cent hemoglobin, and a white-cell count of 12,400 with 61 per cent neutrophilic leukocytes, 25 per cent lymphocytes, 4 per cent large mononuclears and 10 per cent polynuclear band cells. The red blood cells were hypochromic. The blood Kahn reaction was negative. The urine was normal.

\*Assistant in medicine and in charge of the Gastro-Intestinal Clinic, St. Luke's Hospital, New Bedford.

The diagnosis was bleeding peptic ulcer.

The patient's blood was typed. He was placed on a diffied Meulengracht's<sup>12</sup> diet and aluminum hydroxide. stopped vomiting, and his condition in the next several days improved rapidly. On the 7th hospital day, he developed auricular fibrillation, and dullness and diminished breath sounds in the left chest. A film taken with a portable x-ray apparatus revealed a massive collapse of the left lung. The right lung was clear. On the following day, shortly after midnight, the patient began to vomit huge amounts of bright-red blood, and died before any possible treatment could be given.

*Autopsy* (8 hours post mortem). Gross examination revealed blood in the mouth. In the descending portion

or 6 mm. in diameter and admitted the tip of a forceps. A little blood was present in the esophagus. The extension of the aneurysm through the bronchial wall was similar but smaller.

The stomach was greatly distended by blood, much of which was clotted, and the rugae were flattened. The mucosa showed a mild congestion, but no ulcerations were seen in it or in the duodenum.

Microscopic study of the aorta and the wall of the aneurysm revealed many foci of new blood vessels and monocytes in the media and a variable widening of the adventitia in which an increase of fibrous tissue and an invasion of lymphocytes and plasma cells, especially around the blood vessels, were noted. Part of the mass lining the aneurysm consisted of acellular fibrin, frequently in laminated form, and part had a definite thrombus structure. Over the extensions into the bronchus and esophagus, the wall was very thin and consisted of only a few strands. The lung alveoli and the small bronchi contained no blood.

Anatomical diagnoses: syphilitic aortitis, with aneurysm of descending portion of arch, erosion of thoracic vertebrae, erosions into the left bronchus and esophagus, and hemorrhage into the esophagus.

### DISCUSSION

So-called "gas pain" in the abdomen experienced by the patient on a few occasions before admission to the hospital is suggestive of many conditions. It may be a sign of organic as well as functional disease. But when the patient also suffers an episode of severe hematemesis, grave organic disease is almost surely present. Bleeding peptic ulcer is the commonest cause of such symptoms. It is true that a number of other conditions may cause hematemesis—carcinoma or, more rarely, lymphoma or sarcoma of the stomach, aortic aneurysm, mesenteric venous thrombosis, carcinoma of the gall bladder eroding the duodenum, acute esophagitis, esophageal varices due to cirrhosis of the liver, abdominal trauma, thrombocytopenic purpura, carcinoma of the pancreas eroding the duodenum, acute gastritis and Banti's disease. However, such causes of hematemesis are comparatively rare.

Because the physical examination and laboratory findings were essentially negative, except for acute secondary anemia, in the case presented above, peptic ulcer was considered the most probable diagnosis. The patient responded very well to rest and diet, and his general condition was good. On the seventh day, he suddenly developed auricular fibrillation and atelectasis of the left lung. Because of these new findings, attention was focused on the chest, and for the first time there was some doubt. Was the bleeding from the upper gastrointestinal tract, lungs or great vessels? Unfortunately, the patient suddenly died the following day from the massive hematemesis, and there was no opportunity for further study.

FIGURE 1. Post-Mortem Specimen.

The arrow marks the area of perforation of the aneurysm into the esophagus.

The aortic arch was a saccular aneurysm, which extended from the 4th to the 9th thoracic vertebra and had eroded the left side of the 5th to 8th dorsal vertebral bodies. It was adherent to the lower portion of the esophagus at a point 5 to 7 cm. above the cardiac orifice of the stomach and also to the left main bronchus about 1 cm. above the bifurcation, and had extended through the walls of both these structures, forming oval protrusions into their lumens. The defect in the esophageal wall measured by 2.3 cm., and the dome-like elevation of the sac wall was gray except at its lower edge, where there was an opening from the sac into the esophagus, which was 5

## SUMMARY AND CONCLUSIONS

A case of a syphilitic aneurysm of the descending portion of the arch of the aorta, with rupture into the esophagus, is reported.

Although aneurysm has long been recognized as a clinical entity, the silent forms are rather unusual and may present a difficult diagnostic problem, especially if one does not consider such a possibility. Surprise and humility of the attending physician can be prevented if each patient with a severe hematemesis of unknown origin is immediately fluoroscoped in a horizontal position; care should be taken to avoid all abdominal palpation. Thus, no possible harm can be done to the patient, and aneurysms of the aorta can be ruled out.

## MEDICAL PROGRESS

## LICHEN PLANUS: DIAGNOSIS, ETIOLOGY AND TREATMENT

PERRY C. BAIRD, JR., M.D.\*

BOSTON

ALTHOUGH lichen planus has for generations engaged the profoundest interest of physicians the world over, it remains a baffling problem and still constitutes a decided challenge to medical science. The disease is all the more absorbing in its interest because it represents such a clear-cut morphologic entity. It is an appealing and stimulating subject for investigation concerning both interpretation and treatment.

Of the neurogenic, toxic and microbic theories of causation, the first is probably the most popular among writers at present. However, very little convincing evidence regarding causation has accumulated, and no tangible clues to the specific etiology have been found. The treatment has not advanced beyond the empirical stage, and is still chiefly a matter of mercury, arsenic, bismuth and x-ray. However, the use of vitamin B complex, as recommended in a recent publication by Burgess,<sup>1</sup> may prove to be a worthy contribution. The results obtained by Burgess were so favorable as to suggest that his observations will lead to the discovery of some therapeutic method as effective as but less dangerous than some of the procedures now in use. Possibly, this improved form of treat-

ment will be some fraction of the vitamin B complex.

The diagnosis of lichen planus is not difficult in most cases, and yet the behavior of the disease is so varied as to present occasional hazards. Certainly, it is not easy to learn to diagnose lichen planus by textbook descriptions or photographs any more than it is with many other skin diseases. Nevertheless, after one has studied with care a few typical cases, appropriate diagnostic acumen for this disease may be acquired.

The primary lesion of lichen planus is a shiny, flat-topped angular papule, which nearly always presents a violaceous tinge. This lesion is so characteristic that, if examined carefully, it is not likely to be confused with other primary lesions. The papules of lichen planus may develop in rows along lines of scratch. Favorite areas of distribution include the flexor surfaces of the wrists, the inner aspects of the legs and thighs, the penis and the mucous membranes of the mouth and lips. In contrast with the usual tendency toward angular morphology, lichen planus may take the form of ring-shaped lesions, which are encountered especially in the region of the wrists and genitalia. The mucous-membrane changes may be of the nature of silvery stippling, or a flat whitish lacelike network, or whitish patches and streaks. The mucous-membrane lesions may resemble leuko-

Reprints of articles in this series are not available for distribution, but the articles will be published in book form. The current volume is *Medical Progress: Annual, 1940* (Springfield, Illinois: Charles C Thomas Company, 1941. \$4.00).

\*Associate in dermatology, Peter Bent Brigham Hospital; lecturer on industrial hygiene, Harvard University.

plakia, with which lichen planus is often confused. In extent, the disease may vary from a few papules to involvement of practically the entire body surface. The expert must learn to recognize atrophic, hypertrophic, bullous and other forms of lichen planus. Pruritus may vary in degree from mild discomfort to intolerable agony, sometimes leading to suicide.

Lichen planus must be differentiated from other papulosquamous eruptions, such as psoriasis, parapsoriasis and secondary syphilis. No great difficulty should be encountered in distinguishing lichen planus from pityriasis rosea, tinea versicolor and seborrheic dermatitis. A typical case of lichen planus bears no real resemblance to psoriasis. On the other hand, it is worth remembering that many of the lesions in some of the borderline cases of lichen planus may be decidedly psoriasiform. Such lesions show layered, silvery scaling difficult to distinguish from psoriasis and a distinctive erythematous tint strongly suggestive of psoriasis. In psoriasis, the scales are usually thicker and more abundant, and bleeding points may be found. Psoriatic plaques are formed by peripheral extension of the initial papular lesions, whereas lichen planus patches are formed by coalescence of papules. In psoriasis, the elbows and knees seldom escape involvement; in lichen planus, the flexor surfaces of the wrists and the inner aspects of the legs and thighs are areas of predilection. Lichen planus is frequently seen on the mucous membranes of mouth and lips, whereas psoriasis is almost never found in these areas. Both conditions may involve the penis.

In patients who present a papulosquamous skin eruption resembling both psoriasis and lichen planus, the differentiation may remain quite difficult until the skin has been examined completely. Then it is usually possible to demonstrate diagnostic points that swing one's judgment decidedly one way or the other. The finding of characteristic lichen planus papules or typical mucous-membrane lesions quickly settles the matter.

It is advisable to perform blood Wassermann, Hinton and Kahn tests in every case of lichen planus, and only in this way can one be sure to avoid occasional errors in confusing this disease with papulosquamous secondary syphilis.

Lichen planus limited to the oral mucous membranes is not difficult to recognize because of its peculiar morphology, which consists in a whitish stippling, patches and streaks or a whitish lace-like network. Lichen planus of the oral mucous membranes is less likely to be confused with leukoplakia if there are lesions elsewhere in the skin.

Lichen planus may be limited in its distribution to the vulva and in this way becomes of considerable interest to surgeons, gynecologists and obstetricians, who must differentiate it from kraurosis vulvae and leukoplakia. Biopsy must be carried out at times, to aid in the differential diagnosis, particularly if there are no lesions elsewhere over the body to help in arriving at a decision. Because of this circumstance, the histologic picture of lichen planus is probably at times of even greater usefulness to gynecologists than it is to dermatologists.

Authorities agree that the papules of lichen planus possess a histologic structure that may be regarded as pathognomonic and permits accurate diagnosis from biopsy material. A characteristic feature is the limitation of the cellular infiltration to a regular band in the upper cutis.<sup>2</sup> The lower border of this lymphocytic infiltration is sharply outlined, and the upper border lies just subjacent to the basal-cell layer. Among other features of the histopathology, McCarthy<sup>3</sup> includes the following: well-defined, circumscribed (papular) lesions; hyperkeratosis, without parakeratosis; widening of the stratum granulosum; acanthosis, with formation of ill-developed rete cones; hazy outline between epithelium and corium; space formation at the cutaneous epithelial border; dilated blood vessels of the papillary and subpapillary layers; and occasional giant cells (Sabouraud).

Cases of both familial and conjugal lichen planus have been reported. It is of great interest to study these case histories, because of the light that they seem to cast on the etiology of this strange disease. The interpretation of lichen planus as a familial disease was apparently first suggested by Hallopeau and Leredde<sup>4</sup> in 1900, although several observers, including Lustgarten,<sup>5</sup> Brocq<sup>6</sup> and Ormerod,<sup>7</sup> had reported cases with a familial background.

Of approximately 60 cases of familial lichen planus reported in the literature, some of the most unusual have been summarized by Saffron<sup>8</sup> as follows: an acute attack that developed in a mother while she was treating a daughter who had the disease (Brocq<sup>6</sup>); hypertrophic lichen planus in three generations—mother, son and grandson (Joseph<sup>9</sup>); an acute form that developed in two sisters living apart, six weeks after the death of their father (Little<sup>10</sup>); the annular, atrophic variety in two sisters, with the lesions confined to the legs (Samuel<sup>11</sup>); acute lichen planus, in two brothers who were not living together, complicated by glandular and splenic enlargement (Bettmann<sup>12</sup>); typical lesions in a ten-month-old nursing whose mother had lichen planus (Wende<sup>13</sup>); lichen planus verrucosus in a father and son (Von Ken-

nel<sup>14</sup>); lichen planus in the father, son and daughter of a family of four (Veiel<sup>15</sup>); and three brothers who had lichen planus (Scheer<sup>16</sup>).

The occurrence of 4 cases of lichen planus in one family has been reported by Saffron,<sup>8</sup> who concludes that the familial occurrence is an argument for the neurogenic theory of the disease.

The family consisted of father, mother, four sons and a daughter. None of the children had lived with the parents or with one another for ten years. All members of the family were well educated, sensitive and of above average intelligence. The mother, at the age of fifty-two, developed acute lichen planus in 1921 at a time when, presumably, the children were living with the parents. Eleven years later, in 1932, one son, aged thirty-six, developed the disease. In 1936, fifteen years after the mother's first attack, another son, aged thirty-seven, developed lichen planus, and in this same year the mother had her second attack. In 1938, seventeen years after the mother's first attack, still another son, aged thirty-eight, had an acute widespread attack of lichen planus; in the following year, this son had a second attack. The mother's first attack lasted five months, and the second eight months. The first son's attack lasted three months, and the second son's six months. The third son's first attack lasted three months, and his second eight months. All attacks in this family were associated with severe pruritus except for the mild attack in the first son, who had only slight itching. The first son was a salesman, the second a dentist, and the third a factory manager.

Lichen planus of the oral cavity in twins has been reported recently by Epstein<sup>17</sup> as an occurrence previously unknown in the literature. Epstein interprets these cases as evidence favoring both the theory of familial predisposition and the theory of infection. However, his patients displayed indisputable nervous factors and, therefore, could be used in support of the neurogenic hypothesis. It is not illogical to presume that in some of the cases of lichen planus there may be an etiologic interplay of all three of these elements. Abstracts of the 2 cases are as follows:

A 25-year-old man was seen in January, 1939. He had noticed white lesions in his mouth for about 2 months. On examination, he presented numerous confluent reticular lesions covering nearly all the mucous membranes of the cheeks. The appearance was typical of lichen planus, and the additional finding of two annular lesions on the tongue helped to substantiate the diagnosis. In the course of 6 months, the patient consumed 60 cc. of potassium arsenite solution (*U.S.P.*), and the eruption cleared except for a few lesions. Treatment was then changed to vitamin B complex, and good condition was maintained so long as he continued vitamin B complex capsules. Each time he stopped taking these capsules, the disturbance showed a tendency to recur.

The identical twin of this patient was seen in February, 1941, 2 years following his brother. This patient began to notice lesions on the mucous membranes, the middle of the tongue and the lower lip about 8 months after his twin brother had begun to notice symptoms. The similarity of the eruption in the 2 cases was so striking that the patient himself made the correct diagnosis. Examination revealed a picture similar to that described in the case of his brother, with the added finding of a typical annular lesion on the lower lip. The patient treated himself by means of vitamin B complex in dosage up to 9 capsules a day. His condition improved greatly.

Interesting features of these 2 cases of lichen planus are the following: the patients were identical twins; no other members of the family were affected—neither their parents, with whom they lived, nor their brother, with whom they worked, had the condition; both patients were nervous and high strung and admitted hurrying and worrying all the time, and both observed that they were much better when not worried or excited; the clinical picture in the 2 cases was almost identical.

Similarity of symptoms in familial lichen planus has been reported too often to be considered a coincidence. Little's<sup>18</sup> observation of lesions confined to the mucous membranes of the mouth in mother and son corresponds to the cases reported by Epstein.

Spitzer,<sup>19</sup> in 1924, collected from the literature 46 cases of familial lichen planus, in 7 of which husband and wife were affected. Since 1924, 12 additional reports of familial lichen planus have appeared. Of these, only 3 have been conjugal in nature.<sup>20-22</sup>

Of the 10 known cases of conjugal lichen planus, the most recent was reported in 1937 by Goodman and Sulzberger,<sup>20</sup> who encountered this interesting example in their office practice.

The wife, aged 45, when first seen in August, 1935, gave a history of having had a pruritic skin disorder for 8 months. She stated that her husband had complained of itchy lesions on his legs for more than a year prior to the onset of her trouble. Examination disclosed a typical lichen planus consisting in widely distributed, purplish, flat-topped papules. Some of these had an annular grouping. The buccal mucosa showed a network of minute whitish lesions, and there were whitish patches involving the perianal and perivulvar areas. The findings were so typical of lichen planus as to leave no possible doubt regarding the diagnosis. The lichen planus cleared in large part in 3½ months following x-radiation, bismuth and mercury.

The patient's husband was a 53-year-old salesman who was seen, shortly after his wife's satisfactory recovery, in January, 1936. His lichen planus had been slowly extending during his wife's period of recovery under treatment. On examination, he showed typical hypertrophic lichen planus on the legs and ordinary lichen planus elsewhere. There were scattered angular flat-topped papules and occasional ringed forms. One large, annular lesion was present on the penis. Involvement of the lower lip

and buccal mucous membrane left no further doubt regarding diagnosis. This patient recovered satisfactorily following x-ray therapy and mercury. The hypertrophic patches were resistant at the start, but later they were reduced considerably by applications of trichloroacetic acid.

The occurrence of conjugal lichen planus seems to be an argument for the theory of infection.

No discussion of the etiology of lichen planus could be considered adequate without further mention of the theory of infection and the evidence for it. In 25 out of 28 typical cases, Jacob and Helmbold<sup>23</sup> isolated a gram-negative anaerobic bacillus, morphologically resembling those of the colon-typhoid group, which grew freely on a semisolid glucose human-serum medium containing pieces of human tissue. In sections of the lesions, they were able to demonstrate the organism but could not do so in normal skin or in other types of papular skin disorders. By inoculation of the skin of normal persons with this organism, they occasionally succeeded in producing lesions that resembled lichen planus both clinically and histologically.

According to Guttman,<sup>24</sup> modern work has failed to show any connection between the nervous system and lichen planus. Other observers, however, including Ormsby,<sup>25</sup> Pusey,<sup>26</sup> MacLeod<sup>27</sup> and O'Donovan,<sup>28</sup> believe that the disease can be precipitated by mental disturbance. Ramel<sup>29</sup> has reported the case of a woman who developed lichen planus a few days after severe mental trauma; she resisted the usual forms of treatment but recovered following psychotherapy, which brought to consciousness a typical Freudian complex. Eller<sup>30</sup> observed that, during a serious fall in the stock market, acute lichen planus developed among a number of business men who had suffered financial losses. The wife of one of these was affected similarly.

To determine whether certain dermatoses occurred more frequently among nervous patients than among the general population, Goldsmith<sup>31</sup> compared their relative incidence in proportion to the total number of new patients attending the West End Nerve Hospital with their relative incidence in proportion to the total number of new patients attending a general hospital, the University College Hospital. Lichen planus was found by Goldsmith to be only half as common at the nerve hospital.

Culver<sup>32</sup> believes that there is no nervous element in the etiology of lichen planus and quotes in support of this the lack of cases in California during World War I. Since the disease is not reportable, no figures are available to prove whether war actually increases, decreases or fails to affect the incidence. Usually, it is assumed that there has been no increase in lichen planus during

wartime and that this constitutes an argument against the theory of nervous origin. On the other hand, it might be reasoned that war creates a type of stress and strain that crowds out minor financial or family worries and perhaps paves the way for a type of adjustment that does not tend to precipitate attacks of lichen planus.

The generally recognized modern therapeutic approach to lichen planus consists essentially in mercury, arsenic, bismuth and x-ray therapy, as previously mentioned. Other methods of treatment include psychotherapy, injections of extracts of the papules, foreign-protein therapy with colon typhoid vaccines or milk, and lumbar puncture. Local applications are useful only as antipruritic agents. Stelwagon<sup>13</sup> has advised that "the patient is to have the benefit of good, plain food, hygienic living, and, when possible, outdoor life and freedom from mental worry or care."

When the disease is extensive, all forms of injection therapy have an advantage over x-radiation. The bismuth therapy of lichen planus has the advantage that it is less apt to be complicated by untoward reactions than arsenic and mercury are. Bismuth may be administered as the salicylate in oil by intramuscular injection in doses of 1 or 2 cc. at weekly intervals, as in the treatment of syphilis. Bismuth is less effective than arsenic but is advisable for use at the start of treatment because its complications are fewer. Arsenic may be substituted if the therapeutic response to bismuth is inadequate.

The French preparation, Énésol, has been very popular in this country for the treatment of lichen planus and has been considered one of the most reliable forms of therapy. This drug, which is a combination of mercury and arsenic, is administered intramuscularly in doses of 1 or 2 cc. once or twice weekly. Eight to sixteen or more injections may be necessary. The usual reactions to mercury and arsenic must be looked for.

Conrad et al.<sup>34</sup> have reported 25 cases treated by the intramuscular injection of bismuth arsphenamine sulfonate (Bismarsen). They employed twelve to twenty-five injections of 0.1 to 0.13 gm. each. Patients showing signs of a mild toxic reaction to Bismarsen—skin changes, drowsiness, stomatitis and puffiness of the legs—were given large dosage of vitamin C while the drug was continued, and all these reactions disappeared. In some cases, the drug had to be stopped owing to severer reactions. Conrad and his associates treated hypertrophic, localized and generalized types of lichen planus and concluded conservatively that Bismarsen seems to be of value.

Sulzberger<sup>35</sup> recommends that arsenic be administered in the form of a 2 per cent sodium ar-

senate solution containing 1 or 2 per cent phenol. This solution, prepared with sterile water and placed in a sterile container, should be kept in the refrigerator. Injections are given daily by the subcutaneous route. The initial dose is 2 minims, which is increased by 1 minim daily until a dose of 20 to 30 minims (1.5 to 2.0 cc.) is reached. If the eruption disappears or if signs of intolerance develop, the arsenic should be stopped. If necessary, the dosage may be increased to 60 minims (4.0 cc.) daily, and then given in decreasing daily doses until improvement takes place.

Fowler's solution may be given by mouth if the daily subcutaneous injection is not expedient. Sulzberger<sup>35</sup> recommends a mixture containing 1 part of Fowler's solution and 2 parts of compound elixir of pepsin (*N. F.*) or menthol water. Administered in this form, Fowler's solution is more palatable and less irritating to the gastric mucosa. The dose is 10 to 30 drops (0.6 to 2.0 cc.) of the diluted solution three times daily, following each meal.

Arsenic may be administered by mouth in the form of the Asiatic pill (arsenic trioxide). This pill is available in three strengths: 0.002 gm., 0.004 gm. or 0.007 gm. arsenic. At the start, the weakest pill is given three times daily. Later, the dose is increased to the limits of tolerance.

Treatment for four to six weeks is usually necessary before the effects of arsenicals are visible. The treatment, if successful, will bring about relief of itching and disappearance of the lesions, leaving only residual pigmentation and occasionally depigmentation.

In a series of cases of lichen planus some of which had defied the usual treatment for years, Biberstein<sup>36</sup> succeeded in curing 70 per cent by injecting extracts of the papules.

Recent studies by Burgess<sup>1</sup> on the use of vitamin B complex in the treatment of lichen planus are of great interest from the standpoint of both etiology and therapy. His encouraging results are also well worthy of attention because they came about as a consequence of the use of a type of treatment bearing no serious hazards. Burgess points out that the majority of dermatologists have resorted to the theory of neurogenous causation in preference to the parasitic, microbic and toxic. Both he and Goldsmith<sup>31</sup> cite Ramel,<sup>29</sup> who found that violent emotional shock produced the eruption in some cases and that cure resulted from psychoanalytic treatment. Burgess believes that the good results obtained from lumbar puncture and irradiation of certain segments of the spinal column may be ascribed to the psychic value of these procedures. In keeping with these lines of reasoning, Burgess then set out to study the therapeutic effects of vitamin B complex on the theory

of its possible action in relieving the nervous tension of these patients.

Some of the cases studied by Burgess may be briefly abstracted as follows:

CASE 1. Treatment was carried out by means of thiamine chloride given by mouth in daily dosage of 3000 international units and liver extract administered intramuscularly twice weekly in doses of 2 cc. There was lessened irritability in a few days and beginning involution of the lesions in 3 weeks.

CASE 2. Liver extract, given by intramuscular injection in doses of 2 cc. every 2 days, brought about marked regression of lesions in 1 week.

CASE 3. Beminal was given by mouth in daily dosage of 120 cc. and nicotinic acid in daily dosage of 150 mg. Striking regression took place in 4 days.

CASE 4. Marked involution took place in 3 weeks following the use of Beminal by mouth and liver extract by injection.

CASE 6. The response was precisely the same as that in Case 4.

CASE 7. After 6 years' duration, recovery took place in 6 weeks following the use of Beminal and liver extract by mouth.

CASE 8. After 3 years' involvement of the legs and mucous membranes, marked improvement took place in 1 month following the use of Beminal and liver extract by mouth. Complete recovery took place in 2 months.

CASE 9. After 2 years' involvement of the mucous membranes only, complete disappearance of lesions took place in 1 month following the use of brewers' yeast and nicotinic acid by mouth.

CASE 10. A case of 4 months' duration, with involvement of the buccal mucous membrane and tongue, did not respond to yeast, Beminal, riboflavin, nicotinic acid, thiamine chloride, x-radiation, arsenic and mercury.

CASE 12. Lichen planus developed in the course of anti-syphilitic therapy. Brewers' yeast was given by mouth and thiamine chloride by injection. In 1 month, all lichen planus papules were gone.

CASE 14. A case of lichen planus of the dorsal surfaces of the hands of 2 months' duration, with onset following a heart attack, did not respond to vitamin B complex and x-radiation.

CASE 15. Hypertrophic lichen planus located on the inner aspect of the right knee showed improvement with x-radiation but, after 2 months of therapy by means of Beminal by mouth and liver extract by injection, the thickening disappeared completely and was replaced by an area of atrophy.

Burgess states that, in his series of 25 cases, vitamin B complex as a whole, rather than any special constituent, seemed to be effective. He found that such therapy was much less successful if mental unrest continued, and was more effective if nervous stress and strain could be relieved by rest and reassurance.

The itching of lichen planus may constitute a serious symptom; however, it may be entirely absent. The control of pruritus is in some cases beyond the powers of medical science. All forms of therapy known to be of value in bringing about

involution of the lesions are also of assistance in combating the subjective symptoms of this disease. Chloral hydrate is the safest soporific to employ. Sedatives such as phenobarbital may be used, but morphine should be avoided if possible, because of the tendency toward habit formation and its powers of aggravating the itching.

Topical applications in lichen planus are of no value except to help control discomfort. Antipruritic remedies may be made up in aqueous or alcoholic solution or in a vanishing-cream base, and they may contain 0.25 to 1 per cent menthol, 0.25 to 2 per cent phenol, 0.25 to 5 per cent camphor, 0.25 to 1 per cent thymol and 1 to 5 per cent chloral hydrate.

\* \* \*

By full use of all that is known concerning the therapy of lichen planus, gratifying results may be expected in many cases. Some of the patients, however, resist all the usual procedures and suffer from the disease in unabated form for years. There is great need for a more detailed and critical study of these cases from the standpoint of psychiatry, clinical pathology and general medical investigation. There has been scant effort to refute or substantiate the work concerning microbic origin. If the cases were more carefully studied from the historical viewpoint, it is likely that more reports would come forth regarding familial and conjugal incidence, and the interpretation of such cases might become more clear cut.

Lichen planus has many ramifications through the general field of medicine and, as mentioned above, may be limited in its distribution to the mucous membranes of the vulva; it thus becomes of special interest to surgeons, gynecologists and obstetricians. It may appear as a reaction to drugs such as arsenic and the heavy metals, the same chemicals so popular in its therapy. Obviously, it is not purely an external skin disturbance, but a constitutional illness of extraordinary character. Perhaps, the pathologic physiology of lichen planus will not be understood until more is known about what the activities of the sympathetic and parasympathetic nervous systems can do to tissues.

Burgess's<sup>1</sup> work on vitamin B therapy, which gives an entirely new angle to this many-sided subject, may provide a more satisfactory form of treatment, for which there has been a great need as voiced by many dermatologists at the recent meeting of the Academy of Dermatology and Syphilology in New York City. The work of Burgess should be repeated carefully because it really seems "too good to be true." If it is true,

one must find out why vitamin B complex is effective, and it might be of value to investigate whether there is some vitamin B complex fraction of particular value.

A fuller understanding of lichen planus from the neurogenous angle might add a chapter to the rapidly increasing understanding of what the stresses and strains of life can do to the human body, and how these stresses and strains can be offset by vitamins, rest, psychotherapy and other measures.

## CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTE-MORTEM AND POST-MORTEM RECORDS AS USED  
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

### CASE 28251

#### PRESENTATION OF CASE

*First admission.* A fifty-five-year-old Italian barber entered the hospital for study.

Three years before entry, he had an attack of "rheumatism," which soon disappeared. One year before admission, he noticed that dribbling occurred after urination and that his urine, which had not changed in appearance, caused itching of the skin of his legs and penis. This was accompanied by nocturia (once a night) but no other symptoms. Rheumatism recurred nine months before admission, and was characterized by intermittent pain and stiffness of the hands, shoulders, knees and left ankle. The symptoms, which were worse in the morning, were occasionally accompanied by swelling of the joints, with questionable reddening, but no incapacitation; they disappeared in six months. Meanwhile, the pruritus increased, was worse at night, and involved the penis, legs, abdomen and arms, but not the hands. No treatment was given, and relief was spontaneous one month before admission. The patient stated that his wife had noticed some pruritus three months before. Six months before entry, the patient lost his initiative and began to tire easily, and three months later noticed that he felt dizzy if he remained on his feet too long. This symptom finally forced him to stop work. One month before admission, he consulted his physician, who found a positive blood Hinton reaction and started treatment two weeks later. During this time, the patient suffered from an increasing thirst, a nocturia of two or three times a night and a steadily increasing sense of fatigue. Two days before admission, he noticed that his stools had become light brown, and a generalized pruritus developed; there was no jaundice. In addition, there were anorexia and postprandial distension. The patient had lost 8 pounds in an unstat ed period, and for the previous three months had had slight epistaxes after blowing his nose.

Thirty-seven years before admission, he had a penile chancre, which was treated locally. The family history was irrelevant.

On examination, the patient was well developed and somewhat undernourished, and the skin was believed to be more deeply pigmented than is usual for his race. The buccal mucous membrane

was pale, and on the right there was a pigmented gray-black area. A generalized lymphadenopathy was present, with small, shotty epitrochlear, cervical, axillary and inguinal lymph nodes. The heart was not enlarged, and there was a soft blowing murmur at the apex. Examination of the lungs was negative. The liver was just palpable, and a firm, nontender spleen was felt four finger-breadths below the costal margin. There was a suggestion of atrophy of the hands, and the left hand, right foot and right knee were tender on motion and pressure.

The temperature, pulse and respirations were normal. The blood pressure was 150 systolic, 70 diastolic, sitting, and 130 systolic, 70 diastolic, standing.

Examination of the urine was negative. The blood showed a red-cell count of 5,530,000 with a hemoglobin of 65 per cent, and a white-cell count of 2800 with 33 per cent polymorphonuclears, 57 per cent lymphocytes, 2 per cent eosinophils and 8 per cent monocytes; the platelets appeared to be normal. The sedimentation rate was 0.48 mm., the serum van den Bergh was normal, and the blood Hinton and Wassermann reactions were positive. A lumbar puncture revealed nothing abnormal, and the spinal-fluid Wassermann reaction was negative. X-ray films of the chest were negative except for an area of calcification in the right infraclavicular region and questionable areas of calcification at the right hilum.

The patient was placed on an arthritic regime and given 5 cc. of Pentnucleotide. During hospitalization, the white-cell count did not rise above 3900, and for this reason it was deemed inadvisable to institute arsenical antisyphilitic treatment. He was discharged three weeks after admission under the care of his physician.

*Second admission* (four years later). A year after discharge, the patient was seen in the Out Patient Department complaining of generalized weakness, fatigue, joint stiffness and "gas on the stomach." Physical examination was negative except for a coarse tremor of the hands and hyperactive knee jerks. A month later, he returned complaining of swelling, tenderness and pain on motion in the hands and ankles, with pain in the hips and back after standing for a long time. Nocturia had increased to four times a night. The joints of the hands, knees and ankles were thickened and stiff, with tenderness on lateral pressure. Tenderness was also present over the sacroiliac joints and lower spine. A search for foci of infection revealed clear sinuses and chronic tonsillitis; the prostate was not enlarged, but moderately tender, and a smear contained many white blood cells. The patient was given a course of prostatic massage, and in a year the urine cleared and the

frequency subsided. Up to this point, he had had only one course of bismuth; two years before admission, the blood Hinton and Wassermann reactions were still positive. A course of neoarsphenamine was started by his physician, but after three treatments the patient complained of upper abdominal distress, gaseous eructations, fatigue, constipation and clay-colored stools; he developed jaundice and a palpable liver, with tenderness in the right hypochondriac region. The red-cell count was 6,430,000, and the white-cell count 6100 with 47 per cent polymorphonuclears, 43 per cent lymphocytes, 6 per cent eosinophils, 3 per cent monocytes and 1 per cent basophils. The patient was seen in the Out Patient Department two weeks later, when jaundice was still present and the liver was just palpable and slightly tender.

Six weeks before admission, the patient contracted a cold followed by a discharging right ear. He was admitted to the Eye and Ear Infirmary, where examination revealed a right otitis media and mastoiditis; culture of the aural discharge yielded hemolytic streptococci. There was a fine nystagmus to the right. An ulceration was present in the left hard palate, with tender, enlarged cervical lymph nodes. The spleen was enlarged and firm and extended almost to the umbilicus, and there was tenderness in the right upper quadrant. The red-cell count was 3,820,000 with a hemoglobin of 61 per cent, and the white-cell count was 3800 with 58 per cent polymorphonuclears and 42 per cent lymphocytes. Repeated lumbar punctures, including spinal-fluid Wassermann reactions, were negative, but a blood Hinton reaction was positive. On the ninth hospital day, a right simple mastoidectomy was performed, and one week later, the patient was transferred to the general hospital. It appeared that six weeks before admission, after five bismuth injections administered by his physician, a few red nonpruritic, slightly raised papules appeared on the flexor surfaces of both arms and spread to involve the legs in the course of the next week. The bismuth was discontinued, but the papules increased in number and appeared on the face. In the preceding few days, the lesions had faded somewhat.

On examination, the patient was wasted and sick. A diffuse, brownish-red, papular eruption, each papule measuring approximately 0.5-cm., was present on the skin of the forearms, palms, buttocks, knees and calves, but no lesions were seen on the mucous membranes. There was a generalized lymphadenopathy. Examination of the heart and lungs was negative. The spleen was palpable 3 cm. below the level of the umbilicus, and the liver one fingerbreadth below the costal

margin. There was some stiffness and limitation of movement in the fingers of the right hand. Examination of the nervous system was negative.

The temperature occasionally rose above normal, the pulse averaged 95, and the respirations were normal. The blood pressure was 120 systolic, 80 diastolic.

Examination of the urine was negative. Examination of the blood showed a red-cell count of 3,800,000 with a hemoglobin of 65 per cent, and a white-cell count of 4200 with 10 per cent polymorphonuclears, 46 per cent lymphocytes, 40 per cent monocytes and 4 per cent eosinophils; the platelets were normal in number. The red cells were microcytic and hypochromic, with much variation in size and shape; no immature cells were found. The sedimentation rate was 0.92 mm., and a hematocrit reading 31.5; the bleeding and clotting times were normal, and an erythrocyte fragility test was normal. The nonprotein nitrogen of the blood serum was 20 mg. and the fasting blood sugar 90 mg. per 100 cc. The serum van den Bergh was normal, a brom-sulfalein test negative, and a formol-gel test positive; the blood vitamin C level was 0.34 mg. per 100 cc., the plasma prothrombin 95.2 per cent, and the antithrombin 117 per cent. Blood Hinton and Wassermann reactions were positive. A tuberculin test was negative with a dilution of 1:10,000; a Congo-red test showed 63 per cent retention in the serum in one hour. Examinations of the stools were negative.

An x-ray film of the chest was negative. The knees were normal; the hands showed tufting of the terminal phalanges and arthritic changes about the joints consistent with rheumatoid arthritis. There was no periostitis to suggest pulmonary osteoarthropathy. A gastrointestinal series showed slight irregularity in the lower end of the esophagus, but varices could not be demonstrated. The stomach was displaced to the right by a lobulated mass, said to be a markedly enlarged spleen. The liver shadow appeared smaller than usual. X-ray study of the pelvis showed evidence of osteoporosis of the visible bones, but no other evidence of disease. There was a slightly fusiform area of calcification projecting into the true pelvis on the left side. Films of the femurs showed a very small area of calcification in the left popliteal space. There was no evidence of Gaucher's disease.

A biopsy of a lymph node showed chronic inflammation and pigmentation. A skin biopsy showed a rather marked perivascular infiltration containing many plasma cells, a picture consistent with parapsoriasis lichenoides.

During hospitalization, the rash gradually faded, and the mastoid incision healed satisfactorily. Frequent slight epistaxes were noticed. The white-cell count varied between 4200 and 1550. One blood film showed 22 per cent polymorphonuclears, 56 per cent lymphocytes, 4 per cent monocytes, 8 per cent eosinophils, 2 per cent basophils and 8 per cent myelocytes; another film showed 4 per cent myelocytes. The patient was discharged one month after admission to the Out Patient Department.

*Final admission* (five months later). The patient returned to the Out Patient Department three months before admission. His strength had returned to a certain degree, but he complained of finger stiffness that was worse in the morning and of inability to flex the fourth and fifth left fingers. Splenomegaly, hepatomegaly and generalized lymphadenopathy were again noted, and there was slight clubbing of the fingers and edema of the legs. The red-cell count was 4,740,000 with a hemoglobin of 72 per cent, and the white-cell count 2600 with 12 per cent polymorphonuclears, 60 per cent lymphocytes, 16 per cent monocytes, 4 per cent eosinophils and 8 per cent basophils; the sedimentation rate was 1.04 mm. The patient was examined again seven weeks later and felt stronger, but showed the same physical findings except for the disappearance of peripheral edema. One month before entry, he was admitted to the Eye and Ear Infirmary complaining of general malaise, anorexia, fever, loss of weight and a mass on the right side of the jaw that had made its appearance five weeks previously. This mass was an abscess and was incised and drained, yielding purulent material that contained hemolytic streptococci and *Staphylococcus aureus*. Another area of redness and swelling that developed below the major abscess was drained, and a biopsy of the surrounding tissue showed chronic inflammation consistent with gumma. The patient was transferred to the general hospital. It appeared that he had had fairly frequent small epistaxes for the previous two years. In the four years of observation, syphilitic treatment had consisted of twenty-two injections of bismuth and nine injections of arsenicals, with mercury and potassium iodide from time to time. Each attempt was hindered by unfavorable systemic reactions, which included jaundice, pruritus, diarrhea and skin reactions. The patient had lost 34 pounds in an unstated period.

On examination, the patient was emaciated but in no discomfort, and the skin showed a more than racial pigmentation. Over the arms and forelegs were several depigmented scars about 1.5 cm. in diameter, with areas of hyperpigmentation over the legs. The right buccal mucous membrane showed an area of deep-brown pigmentation. A

draining sinus with surrounding induration was present in the right neck below the mandible. The scleras appeared slightly icteric. There was a generalized, shotty, painless lymphadenopathy. Examination of the heart and lungs was negative, except for a soft blowing apical systolic murmur. Examination of the abdomen revealed a smooth, firm spleen, which was not tender and reached to one fingerbreadth below the umbilical level. The liver could be palpated one fingerbreadth below the costal margin in the mid-clavicular line and three fingerbreadths below the xiphoid; it was not tender, and the edge was smooth and sharp. Ascites could not be demonstrated. There was clubbing of the fingers and toes, and the patient was unable to flex the right second, third and fourth fingers completely.

The temperature spiked to 101°F., the pulse was 90, and the respirations were normal. The blood pressure was 108 systolic, 70 diastolic.

Examination of the urine showed a ++ test for albumin. Examination of the blood showed a red-cell count of 4,750,000 with a hemoglobin of 65 per cent, and a white-cell count of 1800 with 1 per cent myeloblasts, 0.5 per cent premyelocytes, 2 per cent myelocytes, 7.5 per cent juveniles, 5 per cent band cells, 4.5 per cent segmented polymorphonuclears, 0.5 per cent large lymphocytes, 58 per cent small lymphocytes, 16.5 per cent monocytes, 3 per cent eosinophils, 1.5 per cent basophils, 1 per cent microblasts and 1.5 per cent Turk cells; the platelets appeared normal. A glucose-tolerance test gave a fasting level of 131 mg., in half an hour 188 mg., in one hour 228 mg., and in two hours 123 mg. per 100 cc. A blood Hinton reaction was positive, and a blood culture negative.

The patient continued to run a fever up to 101.6°F., and an area of fluctuant redness developed beneath the large abscess; within two days, the temperature was 104°F., but the white-cell count remained around 2000 despite the administration of Pentnucleotide. On the eleventh hospital day, the abscess was drained, and sternal-marrow and skin biopsies taken. At the end of this procedure, the blood pressure was 80 systolic, 69 diastolic, the pulse 200, and the respirations 40. That night, the patient had a chill, and the next day failed rapidly, developing coarse bubbling rales and wheezes throughout both lungs, with signs of consolidation at the right base, marked dyspnea and cyanosis, and shifting dullness in the abdomen. He died that day, the twelfth after admission, despite supportive measures and two 500-cc. blood transfusions.

A biopsy of the sternal marrow showed a pronounced increase in cellularity, with a preponderance of erythrogenic forms, among which normoblasts predominated, although there were signifi-

ent numbers of erythroblasts. There were increased numbers of eosinophils and no evidence of obstruction of granulocytic maturation. Megakaryocytes were normal in number. The skin biopsy showed chronic inflammation, and although the appearance was not that of gumma, syphilis could not be absolutely ruled out.

### DIFFERENTIAL DIAGNOSIS

DR JOHN H. TALBOTT: There are several diagnoses to be considered in this case. From the duration of symptoms, I think we are justified in assuming that the patient had a serious and chronic malady. The initial complaints of itching, frequency and dribbling suggest the possibility of diabetes mellitus. This supposition is strengthened by the findings of pigmentation, hepatomegaly and splenomegaly, and one might consider hemochromatosis. The glucose tolerance curve showed a delayed response, not unlike that seen in many types of chronic disease. The urine was negative for sugar at all times, however. I do not believe the patient had either diabetes mellitus or hemochromatosis, and I mention them only to discard them. We are cautioned, on the other hand, that liver disease was present. The fact that in arsenical reaction followed the administration of arsenic, even in the absence of jaundice, points toward a hepatitis. Addison's disease and Grucher's disease should be mentioned in passing as improbable causes of the pigmentation. The data regarding the hepatomegaly and the splenomegaly are impressive. The lower edge of the spleen was felt four fingerbreadths below the costal margin and terminally extended below the umbilicus. This was a large spleen such as may be associated with myelogenous leukemia or Banti's disease.

The leukopenia further points to a blood dyscrasia. The white cell count is known to have risen above 5000 on only one occasion during the four year period, following an acute infection. At times, it was as low as 1500, with a marked diminution in polymorphonuclears, an increase in monocytes and, terminally, an increase in myelocytes. The leukopenia did not respond to Pentamidine administration. Several causes are suggested for the leukopenia. The ulcer in the mouth, following an otitis media and mastoiditis, might make one think of agranulocytic angina. This was seen rather often a decade ago, and in many cases was attributed to the ingestion of amidopyrine. Amidopyrine poisoning must be discarded because we have no evidence that the patient ingested any of the material. The sulfonamides may produce a leukopenia, but again there is no history of ingestion. Finally, cirrhosis of the liver is associated with a persistent leukopenia.

The diagnosis of syphilis, I am sure, we must accept. A penile chancre was treated only locally, and persistently positive blood Hinton and Wassermann reactions were reported. The biopsy was consistent with gumma. The postarsenical hepatitis, which was observed on the second admission, four years after the first symptom, might be explained by one of several mechanisms. An arsenical hepatitis may develop in an essentially normal liver as an idiosyncrasy. Secondly, a hepatitis may be superimposed upon a Laennec's cirrhosis of the liver. Finally, a hepatitis may follow the use of arsenicals in a patient with a syphilitic cirrhosis.

The positive formol gel test, an index of increased globulin content of the serum, confirms the impression that some liver disease was present, although the test may be positive in chronic infections, rheumatoid arthritis and syphilis. The Congo red test was not sufficiently positive to justify a supposition of generalized amyloidosis with liver involvement. A normal person should retain at least 80 per cent of the dye in the serum, a typical case of amyloid disease retains less than 20 per cent. The clubbing of the fingers is interesting. There was no x-ray evidence of periostitis to suggest pulmonary osteoarthropathy. Clubbing is present in 10 or 15 per cent of patients with cirrhosis of the liver. I believe in this case we can attribute the clubbing to hepatic cirrhosis. Diffuse pigmentation may also be seen in cirrhosis. The pigmentation may be so extensive as to make the diagnosis of hemochromatosis an academic point.

The increase in size of the left lobe of the liver intrigues me. McCrie and Craven<sup>1</sup> reported several cases of syphilitic hepatitis with predominant regeneration in the left lobe. The statement in the abstract that the right lobe of the liver was below the costal margin and the left lobe was three fingerbreadths below certainly is suggestive of a syphilitic liver.

Disseminated lupus is a possible diagnosis in this case. The skin rash, a frequent finding in lupus, was probably due to bismuth in this patient. The arthritis and perivascular infiltration are seen in lupus. Leukopenia is also seen, but no mention is made of endocarditis, polysclerosis, a persistent anemia or urinary abnormalities. Before seriously considering a diagnosis of disseminated lupus, I think we should have more leading data than we have.

What diagnoses are we willing to make? We have considered and discarded diabetes mellitus, hemochromatosis, disseminated lupus and Addison's disease. I believe that the patient had pneumonia, terminally. I believe that he had syphilis.

pattern, I should agree, was probably normal, although I think that the mucosa was a little too thick—the mucosa and submucosa together. I do not know what causes a short and narrow colon in an infant a few weeks after birth. I remember that we had a case not too long ago in which a baby had a narrow colon. Somebody told me that the Children's Hospital had found narrow colons in cases with cystic fibrosis of the pancreas.

DR. TRACY B. MALLORY: Have you anything further to add, Dr. Garland?

DR. GARLAND: I am afraid I do not know anything more.

DR. MALLORY: As I understand it, your preference is for an underlying infection whose nature you do not know.

DR. GARLAND: On the premise of diarrhea, yes; otherwise, no.

DR. BUTLER: I think it is only fair to say that the physicians at the Children's Hospital who took care of this patient were as puzzled as Dr. Garland, even though they recognized the importance of the autonomic disturbance. Had Dr. Garland seen the child, he would have been more impressed by her vasomotor instability and autonomic imbalance. These were very striking and are hardly appreciated in a reading of the few sentences that relate to them in the written presentation of the case.

DR. WYMAN RICHARDSON: Do infants of this age ever have idiopathic ulcerative colitis?

DR. GARLAND: This patient was very young for it.

#### CLINICAL DIAGNOSES

Chronic nutritional disturbance.

Pneumonia.

Hepatitis, acute, infectious.

#### DR. GARLAND'S DIAGNOSES

Hyperperistalsis, cause unknown.

Terminal infection, with hepatitis.

#### ANATOMICAL DIAGNOSES

Idiopathic ulcerative colitis, with perforation and peritonitis.

Bronchopneumonia, terminal.

Hepatitis and pyelonephritis, mild.

Pancreatic fibrosis (achylia), early.

#### PATHOLOGICAL DISCUSSION

DR. SIDNEY FARBER\*: Not only the physicians who saw this patient but also the pathologists were disturbed. The main clinical working diagnosis was autonomic imbalance. The final discharge diagnosis was chronic nutritional disturbance, underlying etiology undetermined, pneumonia and acute infectious hepatitis. There was a broncho-

pneumonia, particularly of the left upper lobe, but this was of recent origin.

This is the most important finding: in the region of the transverse colon, there was localized peritonitis, some of which was well organized. In addition, there was diffuse peritonitis from which colon bacilli were obtained. The transverse colon proved to be the site of the previous perforation of the bowel. When the bowel was opened, large numbers of ulcers were found involving the transverse colon, descending colon, most markedly, and also the ascending colon and the rectum, less markedly, however. The involvement of the bowel stopped rather abruptly at the ileocecal valve. The gross microscopic picture was characteristic of ulcerative colitis. There was also a diffuse hepatitis, with a considerable amount of inspissation of bile in the biliary canaliculi. Most of the icterus noted was presumably of the obstructive type. There was a very early lesion of the pancreas acini typical of the picture associated with achylia pancreatica. The mucous glands of the trachea and bronchi and some of the glandular structures of the duodenum showed inspissation of mucus and dilatation of the glandular structures. There was infection, a colon bacillus bacteremia. Whatever organisms might have been there before were certainly obscured by this terminal infection. There was some evidence of older infection in the upper respiratory tract, otitis media and slight, healed pyelonephritis. Whatever the cause of this disease may have been, we have not been able to discover it in this case, although we had an ideal opportunity here, since the symptoms began so early after birth. If one compares this picture with a disease somewhat like it, mucous colitis, and if one recalls the stress that Drs. White, Cobb and Jones† and their colleagues have placed on the probable role of the nervous system, a similar direction may be followed here. The tachycardia, the vasomotor instability and the gastrointestinal disturbance may all be grouped together etiologically from that point of view.

I should like to ask Dr. Mallory what he now considers the cause of ulcerative colitis.

DR. MALLORY: If I were to make a guess, it would be along the same general lines—very definitely against a specific infection.

DR. SCHATZKI: How common is this? Is it very rare in babies?

DR. FARBER: In young infants of this age, yes. We have had two under six months in my experience; this one at three months, and one at two.

DR. BUTLER: Did the one at two display this imbalance?

DR. FARBER: Not to such an extent, but in going over the record, one could find evidence of it.

\*Assistant professor of pathology, Harvard Medical School; pathologist, Children's Hospital, Boston.

## MASSACHUSETTS LICENSES GENERAL HOSPITALS

UNDER the provisions of Chapter 661 of the Acts of 1941, the Massachusetts Department of Public Health has promulgated rules and regulations for the licensing of general hospitals and sanatoriums in Massachusetts, which appear elsewhere in this issue of the *Journal*. Although only two other states, Connecticut and Minnesota, have accepted the licensing of general hospitals as a public function, the principle is by no means new in Massachusetts. As early as 1867, the State Department of Public Welfare was authorized to issue a "license to any person it deems suitable to establish and keep a maternity hospital or ward or other place for the reception, care and treatment of women

during pregnancy or delivery." This action was followed in 1909 by the licensing by the Department of Mental Health of private hospitals for patients with mental diseases.

In spite of this recognition of the public interest in hospitals and in the standards of hospital care, it has, up to the present time, been possible for any person, lay or medical, to establish and maintain a general hospital anywhere in Massachusetts if his application was approved by the selectmen or board of aldermen of the town or city in question. The voluntary supervision of hospitals that has been carried on for many years by the American College of Surgeons and the American Medical Association has been of the greatest value in bringing the standards of hospital care to their present high level but is, of course, effective only in the institutions that choose to avail themselves of it. The Massachusetts Medical Society and the Massachusetts Hospital Association, by their support of this bill, have expressed the opinion that the citizens of Massachusetts are entitled to the assurance that all hospitals, on which they depend for the most vital part of their medical care, meet the generally accepted professional standards of service.

It is not the object of the licensing act or the intention of the regulations adopted thereunder to tell the physicians of Massachusetts what they may or may not do in hospitals but rather to ensure that the practice of medicine in hospitals is carried on in suitable quarters with the aid of properly trained assistants, with adequate equipment and with such laboratory and other auxiliary services as are recognized as essential to modern hospital care. For the further protection of patients, the hospital records must be sufficiently complete to make clear the diagnosis and to show how it is established, and to describe concisely the treatment given, including the type of operation and operative findings. The value of such records to physician and patient alike is universally recognized in professional circles, and adequate medical records have been a major factor in the improve-

ment of hospital services during the past fifty years.

The detailed requirements for maternity hospitals and nurseries may seem unnecessarily exacting to the generation of practitioners who have been accustomed to think of obstetrics as a routine part of general practice. The Massachusetts standards, however, are substantially less exacting than the widely commended maternity-hospital regulations of New York City and of Chicago. Although recognizing the limitations of small hospitals in meeting optimum modern requirements, the new state regulations definitely reflect the recent attempts of the Massachusetts Medical Society and the Department of Public Health to throw every reasonable safeguard around childbirth and further to reduce the excessive maternal mortality rate.

This assumption of responsibility for minimal standards of hospital service by an official agency does not constitute "state medicine." Under the provisions of this act and the adopted regulations, all licensed physicians are free to practise in hospitals in accordance with the accepted standards of their own professional organizations. Hospital licensing on this basis is simply a recognition of the citizens' interest in what has become an essential public service.

---

#### MEDICAL BIBLIOGRAPHY OF SIXTEENTH-CENTURY AUTHORS

SOON after printing began, five hundred years ago, interest was shown in books by medical authors. So far as is known, the first book printed of an exclusively medical nature was published in 1471. In the next ten years, however, over two hundred such books appeared, as listed by Osler in *Incunabula Medica* (Oxford, 1923). Many collections of these items from the early presses are known, the most extensive in America being at the Boston Medical Library. Each book in this section of medical literature has been studied meticulously by various scholars, and even with works issued without title page, date, place or printer, experts such as Dr. Arnold C. Klebs

are able to supply most of the missing data. It seems probable that no group of objects ever devised by man has received so much attention from the learned world. The work still goes on: Klebs's standard short title list, *Incunabula Scientifica et Medica* (Bruges, 1938), is being constantly checked and even augmented; and Miss Margaret B. Stillwell, of Brown University, has only recently completed *Incunabula in American Libraries: A second census of fifteenth-century books owned in the United States, Mexico and Canada* (New York, 1940).

In view of all the work that has been done on fifteenth-century books, it is surprising how little attention has been paid to those published during the sixteenth century. Most libraries, for instance, have isolated their incunabula, but leave the sixteenth-century books in the stacks, sometimes not realizing that these are as precious and rare as many published in the preceding century. Gradual interest in this group of books, and in the larger list of all items published by persons living in the sixteenth century, has resulted in the issue of the first fasciculus of *Bio-bibliography of XVI. Century Medical Authors* (Washington, 1941), by Claudius F. Mayer, the learned editor of the *Index-Catalogue of the Surgeon General's Library*.

In Dr. Mayer's list will be found many unusual features. Its accuracy and completeness, based on the great collections in the Army Medical Library, are assured. In addition to the usual features in a bibliographic list, one will find the location of known copies of individual books, not only in this country, but abroad. Doubtful or nonexistent copies are referred to, and in most cases a brief biographic notice is given of the author, with a reproduction of his portrait.

This project, now only part way through the letter "A," is a welcome addition to bio-bibliographic reference, particularly so in view of the fact that copies of books known to exist in America are referred to, and the essential facts regarding the authors are given. No one is better equipped than Dr. Mayer to carry out this long-needed work,

and he is to be congratulated on the completion of the first section. Plans have been made to issue the fasciculi regularly, the entire work will take several years.

## MEDICAL EPONYM

### PICK'S DISEASE

Dr Friedel Pick (1867-1926), first assistant in the First German Medical Clinic at Prague, presented a discussion, "Über chronische, unter dem Bilde der Lebercirrhose verlaufende Pericarditis (pericarditische Pseudohepaticirrhose) nebst Bemerkungen über die Zuckergussleber (Curschmann) [Chronic Pericarditis—Pericarditic Pseudocirrhosis of the Liver—Simulating the Course of Cirrhosis of the Liver, with Observations on the Frosted Liver (Curschmann)]," in the *Zeitschrift für klinische Medizin* (29:385-410, 1896). A portion of the translation follows:

There is a symptom complex (pericarditic pseudo-cirrhosis of the liver) that simulates one of the mixed forms of cirrhosis of the liver (enlarged liver, marked ascites without jaundice). This results from disturbances in the circulation of the liver caused by a latent pericarditis. These lead to an overgrowth of connective tissue, which produces marked ascites by causing congestion in the portal circulation.

The condition usually occurs in young persons but may be seen in later life.

The following points are to be considered in the differential diagnosis: absence of any etiologic agent for cirrhosis of the liver, a history indicating a previous pericarditis and a previous edema of the legs. Only careful examination of the heart can finally establish the diagnosis.

### COMMITTEE ON MATERNAL WELFARE

#### CASE HISTORY FATAL ECLAMPSIA AND CEREBRAL HEMORRHAGE

A twenty-three year-old primipara was first seen during the seventh month of pregnancy, when she had a blood pressure of 160 systolic, 94 diastolic. Her care from this time on was adequate if not intelligent; she was hospitalized for the remaining weeks of pregnancy. Physical examination on entry was essentially negative, and the past history showed no serious illnesses or operations. Albuminuria did not appear until the thirty-fourth week. The usual pre-eclamptic and toxemic treatment was instituted. The patient did not go into labor until three weeks after the expected date, and the systolic blood pressure ranged from 150

to 160 for the last two weeks, when albuminuria was also constant. After four and a half hours of spontaneous labor, she developed eclampsia accompanied by a cerebral hemorrhage from which she died very shortly. A post mortem cesarean section was performed, but the baby did not live. Autopsy revealed massive cerebral hemorrhage, with signs typical of eclampsia in the liver and kidneys.

**Comment.** There is no excuse for this fatality. Any patient under constant observation for two months who runs a constantly elevated blood pressure and albuminuria should not develop eclampsia and die of cerebral hemorrhage. Although the systolic blood pressure is not recorded as having risen above 160, it is very likely that it did, since it is extremely uncommon for a patient with a systolic blood pressure no higher than this to have a convulsion and fatal cerebral hemorrhage. Patients with toxemia who show a systolic blood pressure of over 150 constantly accompanied by albuminuria when they are in the eighth month of pregnancy, and do not improve with treatment become problems for induction, since kidney damage is undoubtedly progressing. A sharp rise in blood pressure or a diminution in the urinary output calls for immediate delivery. If the cervix is unfavorable for induction, cesarean section is the operation of choice. Depending on the condition of the cervix, either one or the other should have been performed at least two weeks before this patient died.

Post mortem cesarean sections are a moot question. In this case, as so often happens, nothing was accomplished. It is very gratifying that an autopsy was performed. It tells the true cause of the fatality.

### DEATHS

**BUTLER**—FRANCIS J. BUTLER, MD, of Worcester, died June 7. He was in his sixtieth year.

Dr Butler received his degree from Georgetown University School of Medicine in 1908. He was a member of the staffs of St. Vincent and Worcester Hahnemann hospitals and was a fellow of the Massachusetts Medical Society and the American Medical Association.

**COX**—STANLEY C. COX, MD, of Holyoke, died June 7. He was in his sixtieth year.

Born in South Hadley Falls, Dr Cox received his degree from University of Michigan Medical School in 1910. For twenty-one years he served as associate medical examiner and medical examiner for the third district of Hampden County. He was head of the local Medical Division of the Massachusetts Committee on Public Safety in Holyoke. He was a member of the American College of Physicians and Surgeons and a fellow of the Massachusetts Medical Society and the American Medical Association.

His widow, two sons, three daughters, two brothers and a sister survive him.

**WILLIAMS**—**DAVID L. WILLIAMS, M.D.**, of Winthrop, died June 7. He was in his sixty-seventh year.

Born in South Boston, Dr. Williams received his degree from Tufts College Medical School in 1906. He was a former member of the staffs of Harvard and Tufts College medical schools. From 1936 to 1938, he was state commissioner of mental diseases. He was a former member of the Massachusetts Medical Society and the American Medical Association.

His widow, two sons, two daughters and a brother survive him.

## WAR ACTIVITIES

### CIVILIAN DEFENSE

#### CLARIFICATION OF FUNCTION OF RED CROSS AND CIVILIAN DEFENSE UNITS

The following joint statement concerning the respective authority and responsibilities of the local Red Cross chapters and the local Civilian Defense councils was issued on May 18, 1942:

To secure unity of effort and avoid duplication of facilities in meeting civilian needs arising from enemy action, this statement is issued by the Office of Civilian Defense and the American National Red Cross for the guidance of defense councils and Red Cross chapters.

It is the responsibility of local defense councils to see that adequate provision is made for all services required in the event of bombing or other enemy attack. During an emergency period, the commander of the Citizens' Defense Corps will exercise control over all such services.

With respect to emergency medical services and emergency feeding, housing and clothing, provision should be made in each community in conformity with the following principles:

#### EMERGENCY MEDICAL SERVICES

During bombing or other enemy attack, all services are directed from the control center in charge of the commander of the Citizens' Defense Corps. Responsibility for the care of those injured as a result of enemy action rests with the Emergency Medical Service of the Citizens' Defense Corps under the direction of the chief of the Emergency Medical Service.

Red Cross chapters assist the Emergency Medical Service by (a) recruiting and training volunteer nurses' aides, who will be utilized by the Emergency Medical Service at base and casualty hospitals, casualty stations and first-aid posts; (b) furnishing lists of persons trained in first aid to be enlisted by the Emergency Medical Service as members of its stretcher teams; (c) providing dressings, bandages and supplementary equipment as the chapter may decide in consultation with the chief of Emergency Medical Service; (d) equipping and operating emergency ambulances to be assigned to the Emergency Medical Service and to serve under its direction; (e) providing supplementary transportation for walking injured and for Emergency Medical Service personnel. During the emergency period, ambulances and motor units assigned to such transportation service will be under the direction of the chief of Emergency Medical Service or the trans-

port officer. The Emergency Medical Service of the Office of Civilian Defense will not be duplicated by the Red Cross but will be utilized by the Red Cross in natural disasters.

#### EMERGENCY FEEDING, HOUSING AND CLOTHING

In the joint statement, dated April 17, 1942, of the Office of Defense Health and Welfare Services and the American Red Cross it is agreed: "With respect to the emergency period during which special facilities must be made available to meet emergency needs without notice, the Federal Security Administrator will look to the local facilities and resources of the American Red Cross to provide food, clothing and temporary shelter." These services will be provided locally during an emergency period by the Red Cross under the control of the commander of the Citizens' Defense Corps in accordance with detailed plans to be worked out jointly by the commander, the Red Cross chapter and the public-welfare authority.

Defense councils should avoid duplication of these facilities. Where an emergency food and housing corps has already been organized and equipped to the satisfaction of the commander of the Citizens' Defense Corps, its function should be co-ordinated with the functions of the public-welfare authorities and the Red Cross chapter and, if possible, consolidated.

After the emergency period, the appropriate public agencies are expected to undertake the care of civilians in accordance with plans developed in conjunction with the Office of Defense Health and Welfare Services and the Federal Security Administrator. Funds will be made available for this purpose by the federal government through the Federal Security Administrator. Local welfare agencies and Red Cross chapters should be guided in their relations by the agreement signed on April 17, 1942, by the Office of Defense Health and Welfare Service and the American Red Cross.

All Red Cross volunteers enlisted in the emergency feeding and housing service, and all other Red Cross volunteers who are to be in service during and following bombing or other enemy action, will register with the local Civilian Defense volunteer office. The cards of all such registrants are to be marked so as to show that these volunteers are in Red Cross service. In order to obtain necessary freedom of movement during and immediately after enemy action, Red Cross personnel certified to the commander by the chapter for emergency feeding, housing and clothing services will be furnished with identification cards issued to Citizens' Defense Corps personnel and will be authorized to wear the official armband.

This statement supersedes the joint statements of September 4 and December 22, 1941.

NORMAN H. DAVIS, *Chairman*  
American Red Cross

JAMES M. LANDIS, *Director*  
Office of Civilian Defense

## MISCELLANY

### PROMIN IN THE TREATMENT OF TUBERCULOSIS

Success in the use of chemotherapeutic agents in combating infectious diseases revived the hope that eventually a substance will be found that will be useful clinically in the treatment of tuberculosis. Promin, one of the compounds used experimentally, has already been discussed

in the public press. A recent article (Feldman, W. H. Hinshaw, H. C., and Moses, H. E. Promin in experimental tuberculosis. *Am Rev Tuberc* 45 303-333, 1942) summarizes the results obtained in animals with this chemical.

In 1938, sulfanilamide was reported to have an inhibitory effect on the development of experimental tuberculosis in guinea pigs, but subsequent papers held out scant hope that this agent would prove to be a specific remedy for tuberculosis in human beings.

Promin, in its solid form, varies from white to light yellow and is slightly hygroscopic. It is highly soluble in water, and 40 per cent solutions are stable indefinitely and may be sterilized by heat. It is slightly bitter but small amounts may be mixed with the food of animals without impairing their appetite or digestion. Guinea pigs tolerate 1 per cent promin in their foods and will consume from 300 to 400 mg of the drug per twenty-four hours. Increasing the concentration of promin to 2 per cent causes anorexia which interferes with the quantity of food taken.

In the first experiment promin to the amount of 1 per cent was added to the food of 30 guinea pigs. 20 others received the same diet except for promin. Two days after the feeding experiment began all guinea pigs were inoculated subcutaneously with human tubercle bacilli of known strain. On the eighty-fourth day all the animals in the control group had died and 24 of the animals that had received promin were living. Promin was then removed from the diet of 12 of the survivors. After eighty-two more days 13 animals still lived 5 of which had received promin for the entire period (one hundred and sixty-six days) and the other 8 for the first period of eighty-four days only. The purpose of this procedure was to determine if latent tuberculosis would become reactivated when treatment was discontinued.

The value of a chemotherapeutic agent must be appraised not only on survival time, but also on the character of the disease process. With one exception the degree of tuberculous involvement in the animals that received promin was notably less than that in the controls.

Although the results indicated that in many of the animals promin had either prevented the establishment of lesions or caused their eventual disappearance, another effect of the drug which is perhaps of more importance was that exerted on the cellular elements of the lesions. In the vast majority of the animals in the treated group that had lesions the histologic characteristics of the pathologic process apparently were modified favorably. This was especially true of the lesions in the parenchymal tissues. The lesions were usually small and discrete and the epithelioid phase of the reactive process predominated. Necrosis was infrequent, and a tendency of the process toward fibrosis was frequently observed. These features of the morbid process were in marked contrast to those that characterized the disease in the control group of animals. In the latter, the disease was extensive, destructive and progressive.

The objectives of the second experiment were to confirm the results of the first and to determine what effect if any promin might have on a tuberculous infection introduced at the same time as or at varying periods before treatment with promin was begun.

Fifty guinea pigs were selected and divided into eight groups. Group I consisted of 12 animals infected but not treated (controls). Group VIII consisted of 20 animals whose treatment began two days prior to infection. Groups II to VII each contained 8 animals and treatment was begun in relation to the day of infection at various intervals as follows: Group II on the day of infection; Group III after three days; Group IV, after one

week; Group V, after two weeks; Group VI, after four weeks; and Group VII, after six weeks.

All animals except I reacted to tuberculin. Generally speaking the reactions of the animals that received promin were less severe than those of the untreated animals.

Although the general physical condition of the animals remained satisfactory, changes indicative of toxic manifestations were noted in the blood and spleen. Studies as yet incomplete indicate that in guinea pigs, promin may induce a hemolytic type of anemia but with adequate regeneration as indicated by a corresponding reticulocytosis.

The difference in survival times of the several groups was striking. When the last of the untreated animals died one hundred and eighty-nine days after inoculation, 94 per cent of the treated animals were still living. Of the treated animals that died none had sufficient tuberculosis to account for death, and this percentage of deaths might reasonably be considered an average or normal mortality rate for guinea pigs.

Examination of the tissues and organs of the animals showed that all untreated animals were tuberculous; that in 57 per cent of the treated animals no evidence of infection in the visceral organs was found, that, in the remainder of those treated tuberculosis was found (with a few exceptions) of minimal severity, and that 43 per cent of the treated animals failed to show evidence of disseminated tuberculosis.

The failure to demonstrate lesions of tuberculosis in a considerable number of the animals that were treated and the fact that the disease in the treated animals was with few exceptions minimal and nonprogressive indicate that the action of the drug was significant. That fairly comparable results occurred in the treated animals, regardless of whether the administration of the drug was started before or as long as four or six weeks after inoculation with tubercle bacilli was surprising and must indicate that the drug was effectively operative against a tuberculous infection in which morbid changes already were established when administration of the drug was started.

The conclusion of the two experiments is that promin has a deterrent effect on experimental tuberculous infection.

Encouraged by these carefully controlled animal experiments workers have cautiously used promin in the treatment of a few cases of tuberculosis in human beings. Administration of the drug has proved difficult since its toxic effect in man is found to be much higher than that in the guinea pig. In certain cases it has been found necessary to discontinue treatment because of unfavorable symptoms attributed to the drug itself. In other cases in which treatment has been prolonged (five months or more) results thus far show varying effects. In a few definitely demonstrable improvement occurs in others little or no change is observed. In some patients the disease goes on developing progressively, with no apparent effect from the treatment.

It is obvious that a freshly infected guinea pig presents a very different pathologic picture from that of a well-developed human case with destruction of tissue and extensive fibrosis interfering with access of the drug to living tubercle bacilli.

Despite the present lack of convincing evidence of promin's value in the treatment of human tuberculosis there is a definite belief that further trial in skilled hands is indicated. — Reprinted from *Tuberculosis Abstracts* June, 1942.

## THE BEGG SOCIETY

A medical-discussion group, to be known as The Begg Society, has been formed at Boston University School of Medicine in honor of the late Dr. Alexander S. Begg, dean of the school for seventeen years. An annual prize will be offered to the student author of the best scientific paper submitted by a member of the society. Dr. Chester S. Keefer was elected president by the students, and Drs. Joseph F. Ross and Francis M. Forster were named to the prize committee.

## NOTE

At the recent annual meeting of the American Gastro-Enterological Association, held in Atlantic City, Dr. Sara M. Jordan, of Boston, was elected president for the ensuing year.

## CORRESPONDENCE

### REFUGEE PHYSICIANS

*To the Editor:* The Greater Lawrence Medical Association has always been able to handle its local problems, but now we are confronted with a situation that is statewide; and we appeal to the Massachusetts Medical Society for its solution.

Massachusetts has had the reputation for being a "dumping ground" for physicians not wanted elsewhere; once again we have that undesirable distinction, as evidenced by the influx of alien physicians in this state. No doubt the Board of Registration in Medicine is being swamped with their applications.

All the eligible members of our organization have volunteered their services either to the armed forces or to federal services through the Procurement and Assignment Forms. We are ready to sacrifice everything for our country; yet, is it Americanism to penalize us with the thought that our patients, whom we have served with the best of our ability with honest medicine, should suddenly be left to the mercy of ignorant and incompetent alien doctors?

There are over 200 refugee doctors practicing in Massachusetts; and there will be many, many more unless something is done quickly. Recently, we raised the standards of certain unrecognized schools; yet we allow these refugee physicians in Massachusetts, whose class of school and educational background cannot be verified by the examining board.

Major Seeley does not want these men to treat our boys in the army; yet, they are allowed to go into private practice in this hour of trial, when it is essential that the morale of our people be kept at the highest level possible.

Twenty-eight States, either by statute or by a ruling of the examining board, require full citizenship for medical licensure. The Greater Lawrence Medical Association believes that this requisition should be put into immediate effect by the State Board of Registration in Medicine. Within the five-year period required for full citizenship, the alien physician can acquire our ideals, our ethics, and the American way of practicing medicine. Most important of all, this would leave no loopholes for spies, saboteurs or subversive activities. Is this expecting too much from anyone who found existence in another land unbearable? Let us not forget that we are a nation at war.

PHILIP E. ZANFAGNA, *President*

Greater Lawrence Medical Association

126 Haverhill Street  
Lawrence, Massachusetts

## RULES AND REGULATIONS FOR LICENSING HOSPITALS

### HOSPITAL STANDARDS

*To the Editor:* The following are the rules and regulations established under the authority of Chapter 11 Sections 71 to 73 inclusive (Tercentenary Edition), as amended by Chapter 661, Acts of 1941, for the licensing of hospitals and sanatoriums by the Department of Public Health.

These rules and regulations were approved and adopted at a meeting of the Department of Public Health on April 14, 1942.

PAUL J. JAKMAU, M.I.  
*Commissioner of Public Health*

State House  
Boston

\* \* \*

## RULES AND REGULATIONS FOR THE LICENSING OF HOSPITALS BY THE MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

### I. INTRODUCTION

#### A. *Legal authority.*

- Chapter III of the General Laws (Tercentenary Edition) as amended by Chapter 661 of the Acts of 1941 authorizes the Department of Public Health to issue for a term of two years a license, subject to revocation by it for cause, to any person whom it deems suitable and responsible to establish and maintain a hospital or sanatorium which meets the requirements of the department established in accordance with its rules and regulations. The act also provides for the transfer of licensing of maternity hospitals and maternity wards from the Department of Public Welfare to the Department of Public Health.
- As a guide in carrying out this responsibility the department, in accordance with authority granted in Section 72 of the above Act, has adopted the following rules and regulations.

#### B. *Definitions.*

- Under the provisions of this act a hospital or sanatorium is defined as any institution, whether conducted for charity or for profit, which is advertised, announced or maintained for the expressed or implied purpose of caring for persons admitted thereto for purposes of diagnosis or medical or surgical treatment which is rendered within said institution.
- The term "maternity hospital" shall mean any hospital institution or place other than the home of a near relative in which pregnant women are cared for or delivered; the term "newborn nursery" shall mean any room, rooms or ward in such hospital, institution or place in which newborn babies are cared for or are treated.
- The term "department" as used in these regulations shall mean the Massachusetts Department of Public Health.
- Institutions not included in the provisions of the act are those caring for cases of mental diseases and licensed by the Department of Mental Health, including nervous diseases. It does not include convalescent homes or homes for the aged, dispensaries or clinics.

**C. Issuance of license**

- 1 Application for a hospital license must be made in writing upon a form provided by the department. It shall contain the name of the applicant or if an association or corporation the names of any two officers thereof, the name of the hospital, the total bed capacity of the hospital, and in Groups A and B, the number of beds for patients on each floor, the type of hospital to be operated, the location thereof and the name of the person in charge. The license fee of \$1000, payable to the Commonwealth of Massachusetts, must accompany the application.
- 2 The applicant must be a person of reputable character and shall provide references satisfactory to the department.
- 3 Every hospital shall be designated a permanent and distinctive name which shall appear on the application for license, and which shall not be changed without first notifying the department.
- 4 Applications for a license to establish or maintain a hospital or sanatorium shall be considered by the department only if the local board of health has first certified to the department that, from its inspection and examination of said proposed hospital or sanatorium, it is suitable for the purpose.
- 5 The license must be conspicuously posted on the premises.

**D. Revocation of license** A hospital license may be revoked by the department on any of the following grounds, subject to Section 1, Chapter 661, of the Acts of 1941

- 1 Violation of the provisions of the licensing act or of the standards, rules or regulations of the department adopted thereunder.
- 2 Permitting, aiding or abetting the commission of any illegal act in such institution.

Each license shall be returned immediately to the department on its expiration or revocation.

**E. Classification of institutions** For the purpose of these regulations, all institutions licensed under the provisions of this act are classified as follows

- 1 General hospitals with maternity service
- 2 General hospitals without maternity service
- 3 Maternity hospitals
- 4 Tuberculosis hospitals
- 5 Other types of hospitals designated

Hospitals as above classified are divided into the following groups: Group A, 1 to 49 beds, Group B, 50 to 149 beds, Group C, 150 or more beds.

**II. GENERAL REGULATIONS****A. Fire protection** Provisions for fire protection and egress shall be satisfactory to the hospital supervisor of the department and to an inspector of the Massachusetts Department of Public Safety.**B. Sanitation** No system of water supply, sewerage or garbage disposal shall be installed, nor shall such existing system be materially altered or extended until complete plans and specifications have been submitted to and approved by the department. Any existing system of water supply, sewerage or

refuse disposal must meet the requirements for hospitals as established by the department. All construction of such systems must be carried out in accordance with the plans approved by the department.

- 1 **Water supply** The water supply must be of safe, sanitary quality and obtained from a water supply system approved by the department. Running hot and cold water shall be available on each floor of the hospital.
- 2 **Sewage disposal** Sewage shall be discharged into a municipal sewerage system where such a system is available; otherwise, the sewage shall be collected and disposed of in a manner approved by the department.
- 3 **Plumbing** Toilet facilities shall be provided in accordance with the size and number of beds of the hospital. Plumbing drainage and other arrangements for disposal of excreta, and infectious discharges and institutional wastes shall be in accordance with the standards established by Chapter 302, Acts of 1938, for plumbing in buildings owned and used by the Commonwealth.
- 4 **Waste disposal** All organic waste matter resulting from surgical or medical treatment shall be disposed of by incineration. All other refuse shall be stored and removed from the premises in a manner which does not create a nuisance.
- 5 **Garbage disposal** Suitable facilities shall be provided for collection and disposal of garbage at frequent intervals in a manner which does not create a nuisance.
- 6 **Screens** All outside doors, windows and other outside openings shall be screened against flies and mosquitoes, and proper protection provided against vermin.

**C. Heating** Heating plant shall be adequate to maintain a cold weather temperature of 70°F in all rooms used by patients.**D. Lighting**

- 1 Each patient's room should be an outside room with a satisfactory amount of natural light. The window area shall be not less than one eighth of the floor area. All service rooms and working centers shall be adequately lighted. Hallways not otherwise satisfactorily illuminated shall be provided with artificial light giving sufficient illumination to visualize clearly stairways and exits of said halls night and day.
- 2 All permanent electric installation shall comply with the National Electric Code of the National Board of Fire Underwriters and state and local building regulations.
- 3 Emergency lighting facilities must be provided for operating suites and emergency rooms as a storage battery system or battery operated lamps.

**E. Ventilation** Buildings shall be at all times adequately ventilated. Kitchen, bathrooms and service rooms shall be so located and ventilated as to prevent offensive odors from entering patients' rooms and public hallways.**F. Kitchen and food handling** The kitchen, storeroom and other rooms where food or materials used in the preparation of food are stored, exposed or

handled in the process of preparation or consumption shall be in a clean and sanitary condition, and protected from contamination of any kind. Kitchen facilities shall include refrigeration, and perishable goods must be kept at a temperature low enough to prevent deterioration.

G. *Laundry.* The institution shall be equipped with the necessary laundry facilities for the proper cleansing of linen and other washable goods, or satisfactory arrangement be made for such cleansing in a commercial laundry.

H. *Rooms and wards.*

1. Except for nurseries and children's wards, rooms shall be of sufficient size to allow not less than 50 square feet of floor space per bed, and at least 3 feet between beds.
2. Screens shall be provided in wards or multiple bed-rooms in order to secure privacy for each patient. Permanent bed curtains are desirable.

I. *Equipment and furnishings.*

1. There shall be satisfactory provision for the care of clothing, toilet articles and other personal belongings of the patients.
2. A sufficient supply of clean bedding, bed linen, towels and other supplies shall be available for use at all times.
3. There shall be sufficient equipment for nursing care according to type of patients accepted by the institution.
4. Means for signaling nurses must be provided within easy reach of patients confined to bed.
5. Adequate facilities shall be provided for hand washing for personnel.
6. Proper sterilizing equipment shall be provided in accordance with the needs of the type of patients treated.
7. Adequate toilet and bathing facilities shall be provided on each floor in accordance with the standards of the department.
8. There shall be a utility sink on each floor of the hospital.
9. There shall be satisfactory facilities in the utility room for the disposal of contents of the urinals and bed pans, and for cleansing of the same.

J. *Laboratory facilities.* Hospitals in Group A shall provide laboratory facilities for performing routine chemical and microscopic examinations of the urine and complete blood counts. Such clinical laboratory facilities should be under supervision of an experienced clinical pathologist. Such hospitals shall also regularly utilize the services of an experienced clinical pathologist or an approved laboratory for complete clinical, hematological, bacteriological and chemical examinations, as indicated.

Hospitals in Groups B and C shall have a laboratory capable of making the standard hematological, bacteriological, pathological and chemical diagnostic examinations under the supervision of a competent pathologist, or have regular arrangements for obtaining all such services from an approved laboratory.

All abnormal tissues removed at operation, except tonsils and adenoids, shall be examined by the pathologist and a report thereon entered in the patient's record.

K. *X-ray.*

1. Hospitals in Group A which maintain a medical or surgical service shall provide at least a shock-proof portable x-ray machine under the supervision of a competent medical roentgenologist.
2. Hospitals in Groups B and C shall have x-ray equipment capable of performing standard diagnostic roentgenological examinations, such as gastrointestinal series, gall-bladder examinations, chest films and so forth, under the direction of a competent medical roentgenologist. A fluoroscopic unit shall be included.

L. *Drugs.* Drugs, poisons, stimulants and medicines shall be plainly labeled and securely locked in a cabinet, closet or separate room, accessible only to the physician or nurse in charge.

M. *Personnel.*

1. There shall be a competent, well-trained executive officer or administrator with authority and responsibility to carry out the policies of the hospital as authorized by the governing board or owner.
2. There shall be a staff of physicians and surgeons licensed to practice medicine in the Commonwealth of Massachusetts. This staff shall be organized with a chief of staff or medical director. Hospitals of Groups B and C shall be so organized that there shall be a responsible head of each department. There shall be an advisory group of recognized consultants in the fields of medicine covered by the hospital.
3. There shall be a set of by-laws, rules and regulations which are approved by the medical staff, signed by the chairman and secretary and approved by the governing board or owner.
4. There shall be a superintendent of nurses who is a registered nurse, and there shall be at all times at least one registered nurse on duty.
5. The operating room and delivery room shall be under the supervision of registered nurses.
6. The ratio of nursing staff to patients shall be adequate for satisfactory care of the patients.
7. All hospitals shall have a registered physician available on call at all times. (On account of war conditions it is not possible to set up a definite requirement in regard to resident physicians at this time.)

N. *Medical records.*

1. The hospital shall keep complete and accurate records of each patient from the time of admission to the time of discharge. Such patient records shall include: adequate identification data; family, personal, past and present illness history; physical examinations; reports of special examinations, including reports of clinical and pathological laboratory findings and x-ray findings; records of consultations; provisional diagnosis; reports of anesthesia and surgical operations performed; treatment notes and progress notes; temperature, pulse and respiration charts; final diagnosis and discharge note, signed by the physician.
2. In case of autopsy, a copy of the autopsy protocol shall be attached to the record.
3. All notes shall be legibly written or typed and signed.

- 4 A complete list of all births and deaths occurring in the institution shall be sent to the clerk of the town in which the hospital is located, within the first five days of the following month, in accordance with the provisions of Section 6, Chapter 46 of the General Laws
- 5 A summary annual report of the activities of the hospital on forms provided by the department shall be filed with the department within three months of termination of each calendar year
- 6 The following additional records shall be kept in a form and manner prescribed by or acceptable to the department: record of admissions, register of deaths, daily census record, clinical records, narcotic registers of records, records of physicians' orders, autopsy protocols

### III REGULATIONS FOR SURGICAL DEPARTMENT

In addition to the general regulations all hospitals in which surgical operations other than emergency operations are performed shall conform to the following regulations

A. *Operating room* The operating room shall have impervious floor and washable walls. There shall be a satisfactory means of illumination of the operative field as well as general illumination. There shall be facilities for scrubbing preferably in a separate room, with running hot and cold water delivered through spray faucets and controlable without use of the hands. Heating shall be adequate to maintain a temperature of 60°F in the operating room. A suction apparatus shall be available.

B. *Surgical equipment* The hospital shall constantly have on hand sufficient instruments to perform an abdominal operation and a supply of sterile dressings and linen. There shall be an operating table so built that it can easily be placed in lithotomy or in Trendelenburg position with the patient on the table.

C. *Sterilization* The equipment shall include an autoclave capable of operation under 15 pounds steam pressure and a boiling water sterilizer. An acceptable aseptic technic shall be observed in all major or minor operative procedures. Proper care shall be taken to prevent contamination of the surgical field, sterile tables or operating team by visitors. Likewise, after an operation on a septic case the operating room shall be thoroughly cleansed in a manner adequate for the type of contamination existing.

D. *Anesthesia* There shall be satisfactory equipment to allow the administration of nitrous oxide, oxygen and carbon dioxide. In operating rooms using anesthetic gases capable of exploding under certain conditions of concentration, humidity and so forth, all reasonable precautions shall be taken to avoid this hazard.

E. *Staff* Surgical operations shall be done only by physicians designated by the hospital as qualified to do surgery.

F. *Preoperative care* Operations under a general anesthetic (inhalation, spinal, intravenous or rectal) shall not be performed nor a general anesthetic given until the patient has had a physical exam-

ination including examination of the chest for respiratory infection or cardiac disease and including a urinalysis with tests for albumin and sugar. The results of these examinations, together with the preoperative diagnosis, shall be entered in the patient's record.

G. *Operative records* An accurate and complete description of the technic of operation and the findings, and a statement of organs or tissues removed, together with the postoperative diagnosis, shall be entered by the surgeon in the patient's record immediately following the operation.

H. *Postoperative care* After the administration of a general or spinal anesthetic, patients shall be constantly attended by a nurse until they have regained consciousness or until the effects of the anesthetic have worn off. After any major operation, adequate nursing services shall be provided so that patients are closely watched and given all necessary care.

### IV REGULATIONS FOR MATERNITY HOSPITALS OR SERVICES

All hospitals with maternity service as defined on page 1 of these regulations shall conform to the following standards in addition to those specified in the general regulations.

It will be noted that the regulations for maternity hospitals are more detailed and the standards are higher than those applying to other types of hospital service. This is because of the vital role of proper care in the reduction of maternal and infant mortality. Much attention has been given in recent years to efforts to reduce maternal and infant mortality through placing the pregnant woman under medical care early in pregnancy, educating her in the hygiene of pregnancy and the puerperium and stressing the importance of hospital delivery. Unless maternity hospital standards are kept at a reasonable level, this effort cannot be wholly effective. These regulations are intended not to hamper the physician with unnecessary red tape nor to dictate to him how he shall conduct his obstetrical work and keep his records but to aid him by pointing out what are regarded by leading obstetricians and hospital administrators as the essentials of good hospital delivery service and care of the newborn.

#### A. *Maternity units*

- 1 The maternity unit shall be segregated from any medical or surgical service. This shall not preclude the treatment of uninfected medical or surgical cases in separate rooms on a maternity unit.
- 2 There shall be at least one delivery room and hospitals with multiple bedrooms or wards shall provide in addition one or more labor rooms.
- 3 Isolation quarters shall be provided for infected mothers. A mother shall be considered infected if
  - a She has a communicable disease or is suspected of such or if she is a carrier.
  - b She nurses an infected infant.
  - c She is delivered outside the maternity unit of the hospital in which she is afterward cared for.
  - d She has an unexplained fever during the puerperium.

4. Labor, delivery room and all other facilities used for infected mothers shall be separate from, and not used for, non-infected patients until they are made safe by cleansing and sterilization.
  5. Equipment of a maternity unit shall include a bed-pan sterilizer or individual pans which shall be adequately sterilized for each patient.
  6. All nurseries, isolation quarters, formula rooms, examining rooms, labor and delivery rooms, and maternity rooms or wards shall have adequate facilities for the scrubbing of hands, and receptacles for the efficient temporary disposal of soiled linens and waste.
  7. Delivery-room technic must be in accordance with recognized and approved obstetrical technic. Equipment shall be such as to make this possible. Oxygen for resuscitation and facilities for blood transfusion shall be available.
  8. The advice of an obstetrical consultant should be obtained preceding any major operation or abnormal, induced or complicated labor.
  9. Before the removal of the mother or baby from the delivery room each infant shall be labeled with some adequate method of identification approved by the department.
  10. The 1 per cent solution of nitrate of silver furnished by the Department of Public Health shall be instilled in each eye of every infant before it leaves the delivery room.
  11. Should one or both eyes of an infant become inflamed, swollen and red, or show a discharge, the hospital shall report the case to the local board of health.
  12. When such a case is discharged from the hospital, a report in writing shall be sent within six hours after such discharge to the board of health of the city or town to which the infant is to be taken. This report shall state whether the infant is discharged cured or uncured, also the street and number to which the infant is to be taken.
  13. Each hospital shall act in conformity with the provisions of Chapter 119, General Laws (Tercenary Edition), as amended by Chapter 629, Acts of 1941, for the protection of children, and shall not be concerned in, encourage or permit any unlawful disposition of an infant or any arrangement whereby an infant may be deprived of any of his legal rights or be abandoned. The hospital shall not be concerned in placing infants apart from parents or guardian, and if the superintendent knows of any such arrangement he shall at once report the case to the Division of Child Guardianship of the Department of Public Welfare.
  14. Upon the discharge of each infant from the hospital, a mark specified by the department, which will serve to identify the infant, shall be placed upon the shirt, diaper, band, dress and other covering.
  15. Any neglect or evasion of these rules, or any collusion by the hospital with any person for their evasion, shall constitute sufficient cause for the revocation of the license.
- B. *Newborn nurseries.*
1. There shall be a separate nursery for newborn infants, with adequate space, light and ventilation.
  2. Bassinets shall be so spaced that they are separated by at least 6 inches on all sides. Suspension of bassinets on double-tier racks shall be prohibited.
  3. Isolation quarters shall be provided for infected infants. An infant shall be considered infected if:
    - a. It has a communicable disease or is suspected of such, or is a carrier.
    - b. If delivered of an infected mother.
    - c. If delivered outside the hospital.
  4. Common or group carriers for infants shall be prohibited.
  5. Cloth or paper covers on a common dressing table or scales shall be changed for each infant.
  6. Running hot and cold water and suitable receptacles for the disposal of waste and soiled linens shall be provided in or adjacent to each nursery.
  7. Individual sterilized rectal thermometers shall be provided for each infant. All examining instruments should be sterilized before use for each infant. Gauze, cotton and so forth shall be sterilized and kept stored in sterile containers in each nursery.
  8. All linens used in the nursery shall be kept separate from those used in other parts of the hospital and shall be laundered separately.
  9. All physicians and nurses and any others who must enter any part of the nursery shall scrub their hands thoroughly and put on a clean gown, headgear and mask.
- C. *Premature nurseries.* All hospitals with maternity service must provide the minimum equipment listed in this section for the care of premature infants. All standards specified in the section on newborn nurseries must be met in the premature nurseries; in addition, the following provisions shall be made:
1. The premature infant must be cared for in a heated bed or incubator, which must be available in all nurseries.\* (In a room with temperature and humidity control designed for the care of premature infants the heated bed is not required.)
  2. Some type of heated bed should be ready in the delivery room, in which the infant can be transported to the nursery.
  3. Oxygen must be quickly and easily available in both the delivery room and the premature nursery.
  4. Suction apparatus should be easily and quickly available in both the delivery room and the premature nursery.
  5. The premature should be cared for in a separate premature nursery or should be segregated in the newborn nursery.
  6. Isolation facilities must be provided for the infected premature infant.
  7. Nurses assigned to the care of premature infants shall not care for infected infants at the same time. Each nurse shall wash her hands for five minutes and put on a clean gown and mask before entering the premature nursery.
  8. Visitors must not be allowed in the premature nursery.
  9. The premature infant must not be discharged until it weighs more than 5 pounds and its condition is such that it will presumably survive home care.

\*A satisfactory incubator can be constructed for approximately \$10.00.

- 10 Before discharge, arrangements for continuous medical supervision by a physician or well child conference shall be reported by the staff physician to the superintendent

**D Formula rooms** Each maternity hospital shall have adequate facilities for the preparation of formulas for infants—where practical in a separate room. Proper sterilization and refrigeration equipment shall be provided in the formula room or in an adjoining room. Aseptic technic must be maintained in use of containers and utensils and in formula preparation

**E. Personnel in maternity units and nurseries**

**1 Nursing staff**

- Sufficient nurses shall be provided for the adequate care of mothers and infants. These shall be under the supervision, both night and day of a graduate nurse. After July 1, 1942, all new supervisors shall be graduates of an approved school of nursing and registered in Massachusetts.
  - Nurses assigned to nursery and formula rooms shall not come in contact with any infected patient or with isolation quarters.
  - Private nurses must comply with maternity unit rules and regulations.
  - No person shall enter the nursery except those immediately concerned with the care of the newborn.
- 2 All personnel in contact with patients and all food handlers shall be examined on assignment and annually thereafter by a physician designated by the hospital management and shall be certified as showing no evidence of communicable disease. This examination shall include a chest roentgenogram.
- 3 All personnel shall immediately report any illness, or signs of infection, however slight, and shall be excluded from the maternity unit until seen by a physician.

**F Visitors and visiting hours**

- Visiting hours to maternity services shall be set at such a time as not to coincide with the hours when the newborn infants are in the maternity ward or private rooms for nursing by their mothers. There shall be a minimum of visiting permitted on all maternity services.
- Children under fourteen years of age shall be prohibited from admittance to any maternity unit at any time.

**G Records** Complete and detailed case history records shall be kept of maternity patients and infants. The following outline gives the minimum information which should be included in any hospital maternity record. It is not of itself a record form.

**1 Maternal record**

Patients name, occupation, age, color, nativity, religion, gravida, address, husband's name and occupation, date of admission and service to which admitted, general history (medical, surgical, Wassermann tests), general physical examination on admission, obstetrical history of each pregnancy, describing prenatal care, month started and regularity, and all abnormalities.

Obstetrical examination on entrance to service including temperature, pulse, respirations, blood pressure, urinalysis (albumin and sugar), fetal heart rate and abnormalities.

Labor a satisfactory description of labor should be recorded, including time of onset, and if induced reasons therefor, maternal pulse rate during all stages, fetal heart rate. All rectal and vaginal examinations made in any stage of labor must be recorded as to time and findings, and by whom made. Analgesia or anesthesia and medication in any stage should be recorded as to type, amount and time given. In addition for each stage the following should be recorded:

First stage duration, type and frequency and character of pains, rupture of membranes, time whether spontaneous or artificial examinations, and anesthesia or analgesia as outlined in above paragraph, fetal heart rate.

Second stage duration, examination and anesthesia or analgesia described as outlined above, fetal heart rate, presentation, method of delivery—if operative reasons, descriptions and names of consultants and operator must be given, description of lacerations, description of any complications.

Third stage duration, method of placental delivery, hemorrhage, condition of uterus of mother and infant one hour after delivery. Name of physician who did delivery and assistants.

Postpartum course: chart of temperature every four hours when awake for five days, then twice daily, if any complication arises, resume four hour chart; medication and treatment, progress of involution of uterus, type of lochia, condition of breasts and nipples, general condition of mother (including condition of uterus) at time of discharge, date of discharge.

**2 Pediatric record**

Infant's name, sex, color, date and hour born, birth weight and length, period of gestation, mother's name, address.

Description of complications of pregnancy or delivery, condition at birth, including color, quality of cry, method and duration of resuscitation.

Findings of initial general physical examination, description of any postnatal disturbances.

Progress notes, chart of temperature, pulse and respirations at least twice a day if no complications arise, weight chart recording weight at least every other day, condition of cord from day to day, color from day to day, feeding character and frequency of stools, vomiting, any unusual symptoms.

Findings of physical examination on discharge with recommendations.

Physician's name.

**V REGULATIONS FOR TUBERCULOSIS SANATORIUMS**

All provisions of the general regulations shall apply to tuberculous hospitals and sanatoriums. In addition, the following special requirements must be fulfilled:

**A Equipment**

- 1 Each hospital, irrespective of its size, shall have x-ray equipment capable of producing satisfactory

diagnostic roentgenograms of the chest and making fluoroscopic examinations of the chest.

2. There must be apparatus for the administration of artificial pneumothorax.

#### B. Procedures.

1. Each patient shall have a medical history taken and physical examination made by a physician within four days of admission.
2. All patients with expectoration shall have their sputum examined for tubercle bacilli by direct smear on admission, and if the smears are negative, more sensitive methods for the detection of tubercle bacilli (concentration tests, cultures or guinea pig inoculation) must be employed. Sanatoriums with less than 50 beds may arrange to have a laboratory, approved by the department, perform these tests. All patients who are raising sputum, with the exception of progressive far-advanced cases, should have their sputums examined at least once a month.
3. All patients shall have a chest roentgenogram on admission and as often thereafter as is necessary to detect changes in the pulmonary lesions, with a maximum interval of once in four months, and within two months of discharge.
4. Patients shall be provided with cardboard sputum boxes and paper handkerchiefs or satisfactory substitutes therefor, which shall be destroyed by incineration after use. Reasonable precautions shall be taken against exposing personnel and other patients to infection from sputum-positive cases.

#### C. Personnel.

1. Each hospital shall have either on its resident or visiting staff at least one properly qualified tuberculosis specialist.
2. Whenever indications exist, examination and treatment by a consulting nose and throat specialist shall be provided. Arrangements shall be made for the performance of bronchoscopy whenever, in the opinion of the staff, this procedure is indicated.
3. The services of a dentist shall be provided regularly and as needed.
4. All personnel regularly employed in the hospital who come in contact with patients shall have a roentgenogram of the chest at least annually.

## BOOK REVIEWS

*Essentials of Endocrinology.* By Arthur Grollman, Ph.D., M.D. 8°, cloth, 480 pp., with 74 illustrations. Philadelphia: J. B. Lippincott Company, 1941. \$6.00.

This book is intended as a broad survey of the entire subject of endocrinology for the "average medical reader," and serves as a good up-to-date summary of this rapidly developing field.

The author is primarily a pharmacologist and has been a chemist and physiologist. It is not surprising, therefore, that his approach is that of the laboratory experimenter rather than that of the clinician.

After an introductory chapter, the author takes up each endocrine gland in turn, grouping together the glands of the cranial cavity, the branchiogenic organs, the abdominal endocrines, the hormones of the reproductive system and the hormones derived from nonendocrine organs. In discussing each gland, he gives a rather detailed account of its embryology and histology, and draws heavily on the available data from comparative anatomy. The physiology and the principal experimentally proved facts are concisely presented, whereas all theories and ideas not conclusively proved experimentally are given short shrift.

Many widely held notions are dismissed as without valid foundation. Thus, the conception of the pituitary gland as secreting numerous separate hormones "is undoubtedly erroneous, and future investigation may reveal that the hypophysis elaborates a single hormone which is responsible for all of the manifestations of the gland."

The clinical aspects of endocrinology, including therapy with the available preparations, are by no means neglected; yet they are given relatively less consideration than the "average medical reader" might wish. There are a few statements that might be questioned. For example, in the treatment of myxedema, the author states that it is "safe to initiate therapy with a daily dose of 2 grains [of thyroid]." In discussing the causes of destruction of the anterior portion of the pituitary gland in Simmonds's disease, he states that "the most common one is emboli originating usually in the parturient uterus which occlude the terminal arteries of the anterior hypophysis."

On the whole, this is a well-written, critical textbook. There are well-chosen references at the end of each chapter, a good index, and a table, in the front and back linings, of some commercially available endocrine products and their standardization. Unfortunately, there are numerous typographical errors.

*The Biologic Fundamentals of Radiation Therapy.* A textbook. By Friedrich Ellinger, M.D. With a preface by Maurice Lenz, M.D. English translation by Reuben Gross, M.D. 8°, cloth, 360 pp., with 79 illustrations. New York: Elsevier Publishing Company, Incorporated, 1941. \$5.00.

The book covers more ground than its title implies. In addition to the biologic fundamentals, it also delves into the underlying principles of electrophysics that pertain to this subject. Although the part of the light spectrum that is therapeutically most important will remain invisible to the *physical* eye of the reader, this book will enable him to see it with his *mind's* eye.

The introduction describes the electromagnetic spectrum and the combination of the quantum and wave theories of light. A section on biologic considerations or the action of radiation on living matter follows. This leads to discussions of absorption of radiation by the respective medium and of the effective quantum energy as a function of wave length at the site of absorption. In the light of these and similar basic principles, roentgen-rays, the gamma radiation of radium, the Grenz rays (ultrasoft roentgen rays), ultraviolet rays and the action of visible light are successively treated.

The technic of application of these energies to the various tissues, organs and systems of the body is discussed in the light of the previously mentioned physical principles and biologic effects.

Important factors, beneficial and injurious, that are manifested by the local reaction of the skin, the portal of entry of these rays, and their indirect effects on the deep-seated structures of the body are taken up in a logical and scientific manner.

The author is as honest in his statements of fact and hypothesis as he is profound in his discussion of the underlying theory. He is as generous in the details of technic of application as he is broad in his consideration of the various physiologic and pathological problems that confront the physician in his practice of medicine. The reviewer therefore heartily endorses this work to the student, general practitioner and specialist alike. Radiation therapy, particularly that employing the ultraviolet ray, has been used widely but not always wisely. This treatise may help to remedy the situation.

## THE TREATMENT OF PERNICIOUS ANEMIA: A NINE-YEAR STUDY OF MAINTENANCE REQUIREMENTS, WITH A NOTE ON THE EFFICACY OF PURIFIED LIVER EXTRACTS IN THE CONTROL OF NEURAL LESIONS\*

MAURICE B. STRAUSS, M.D.,† ARTHUR J. PATEK, JR., M.D.,‡ FREDERICK J. POHLE, M.D.,‡ HERBERT J. FOX, M.D.,§ AND JOSEPH H. BUCHENAU, M.D. |

BOSTON

IT has been well established that the patient with Addisonian pernicious anemia may be maintained in complete remission with "adequate" liver extract administered parenterally. Furthermore, it is well known that such treatment must be continued throughout the remainder of the patient's life. What constitutes "adequate" therapy, however, is not well established. Although probably over 90 per cent of patients with pernicious anemia may be maintained satisfactorily if they receive a minimum of 1 U.S.P. unit of liver extract daily, generally administered as 15 units every fortnight or 30 units monthly, there is a question whether this amount is in excess of the requirements of most patients. Intervals longer than one month between injections are considered inadvisable for most patients, since it has been shown that relapse may occur as soon as eight to twelve weeks after the injection of even massive doses of liver extract.<sup>1,2</sup> Whether benefit derives from shorter intervals than one month between injections is not known.

In an endeavor to clarify these problems, an analysis has been made of the blood levels of 80 patients with pernicious anemia who received liver extract in varying amounts and at varying intervals during a period extending from five to nine years. The minimum length of any one mode of treatment was one year, and no patient has been in-

cluded in this study who was not treated for at least five years. During the first part of this study, the liver extract originally described by Strauss, Taylor and Castle<sup>3</sup> was employed in uniform dosage of 10 cc. per injection,<sup>4</sup> at intervals of one to four weeks. The average red-

TABLE 1 Effect of Varying the Time Interval between Injections of Liver Extract

41	15	3	4.5	95
	15	4	4.5	93

cell counts for patients receiving injections at intervals of one, two, three and four weeks were 4,780,000, 4,720,000, 4,850,000 and 4,750,000, and the hemoglobin levels were 91, 92, 94 and 91 per cent respectively (100 per cent being equivalent to 15.6 gm. per 100 cc.). To facilitate comparison, the patients were divided into six groups, each group consisting of patients who received injections at different intervals (Table 1). It is apparent that varying the interval between injections

The authors are indebted to Dr. J. C. Castle for his critical review of the manuscript, and to Dr. J. C. Castle for his critical review of the manuscript.

from one to four weeks was without effect on either the red-cell count or the hemoglobin level.

In 1938, three changes were made: a uniform interval of four weeks between injections was adopted for all patients; a shift was made from the relatively dilute type of liver extract previously employed to Solution Liver Extract Purified, Lilly, containing 15 U.S.P. units to each cubic centimeter; and blood for examination, formerly obtained by puncture of the ear lobe, was removed by venipuncture without stasis. It has been pointed out that, in pernicious anemia at least, venous blood contains approximately 5 per cent less hemoglobin and 250,000 fewer erythrocytes per cubic millimeter than capillary blood.<sup>4</sup> The amount of extract given at each injection was 10, 15, 20 or 30 units. The average red-cell counts maintained with each of these doses were 4,540,000, 4,470,000, 4,470,000 and 4,520,000, and the hemoglobin levels were 85, 87, 87 and 88 per cent respectively. At the end of 1939, the amount of extract received by 45 of the patients was increased by 50 per cent. Table 2 shows the ab-

complained of feeling less well during the third or fourth week after the injection, and during the period immediately preceding the next injection, and a few actually had some subjective manifestations of glossitis that were abolished after the injection.

Since this study was completed, we have adopted a uniform maintenance dose of 15 U.S.P. units of purified liver extract every four weeks for all clinic patients. In the period of eighteen months in which this regimen has been in effect, we have encountered no relapses in the blood, gastrointestinal or nervous systems, either objective or subjective.

### DISCUSSION

There seems to be little doubt that individual maintenance requirements for liver extract vary widely in patients with Addisonian pernicious anemia. The determination of the requirement is a difficult task often necessitating years of observation. It is not, in general, a feasible procedure in the routine handling of a patient with pernicious anemia. It has repeatedly been stated that one of the criteria of adequate treatment is the maintenance of normal red-cell values. This is, of course, quite correct, although often difficult to apply in actual practice for several reasons. One of these is that although the *average normal* red-cell count is in the neighborhood of 4,500,000 to 5,000,000, there are rare persons whose *normal* values are persistently under 4,000,000 and others whose normal values are over 6,000,000. A second difficulty, only recently appreciated,<sup>7</sup> is the fact that a single red-cell count performed with satisfactory technic in the usual manner at an approximate level of 5,000,000 is significant only within a range of 1,600,000. In fact, a difference of over 1,000,000 may be expected to occur once in every twenty pairs of consecutive red-cell counts. The performance of duplicate determinations on each observation only increases the range of significance to 1,100,000 and quadruplicate counts to 800,000. A mean of twenty counts is significant within a range of 340,000, but this is hardly a practical procedure. Price-Jones curves, admittedly the most accurate determination of red-cell normality, are too laborious for routine use. Estimation of the mean corpuscular volume, depending as it does on the red-cell count and hematocrit determination, appears to be subject to even wider variation than the red-cell count alone.

In view of these difficulties, we have set up the following procedure in our clinic for determining adequacy of treatment:

If the red-cell count is persistently under 4,000,000, greatly augmented doses of liver extract are employed at short intervals — such as 30 to

TABLE 2. *Effect of Increasing the Amount of Liver Extract Given at Each Injection.*

NO. OF PATIENTS	AMOUNT OF LIVER EXTRACT GIVEN AT EACH INJECTION	INTERVAL BETWEEN INJECTIONS	AVERAGE VENOUS RED-CELL COUNT	AVERAGE VENOUS HEMO- GLOBIN
	U S P. units	weeks	$\times 10^6$	%
25	10	4	4.5	85
	15	4	4.5	87
20	20	4	4.5	87
	30	4	4.5	88

sence of effect of this procedure on the red-cell count and hemoglobin level.

In the first part of these observations, no case of blood relapse occurred with the increased interval between injections, and in the second part there was no statistically significant improvement in any patient's blood values with the 50 per cent increase in dose.

Additional evidence of the adequacy of the treatment employed is to be found in the facts that no patient with subacute combined degeneration of the spinal cord suffered a neural relapse and that no patient without spinal-cord manifestations developed neural lesions during the period of observation.<sup>5</sup>

It may also be stated that the concentrated liver extract employed during the last three years has been as effective in controlling the neural lesions as the less purified extracts previously used.<sup>6</sup>

When injections of 10 cc. of crude extract or 10 U.S.P. units of purified extract were given at intervals of three or four weeks, certain patients

75 U.S.P. units weekly for two or three months; if this results in consistently higher blood values, one concludes that the previous therapy was inadequate.

If glossitis occurs, the treatment is considered inadequate, irrespective of high red-cell levels.

If neural lesions progress unfavorably, the treatment is considered inadequate, irrespective of red-cell counts.

If the patient lacks what he considers a satisfactory sense of well-being on any given amount of treatment and regains a feeling of better health when, unknown to him, he is receiving a larger amount of extract, the original treatment is regarded as inadequate.

### SUMMARY

Eighty patients with Addisonian pernicious anemia were studied for from five to nine years while under treatment with liver extract parenterally administered.

In these 80 patients, no difference in blood levels was detected when the time interval between injections of the same amount of dilute liver extract varied from one to four weeks. Seventy-five patients subsequently received concentrated liver

extract by injection. No difference in blood levels was noted as a result of this change, and there was no case of neural relapse.

No difference in blood levels between patients receiving a minimum of 10 U.S.P. units every four weeks and those receiving larger amounts was detected. It is nevertheless probable that certain patients require more liver extract than this amount, particularly in the presence of infection or severe damage to vital organs.

## PNEUMOCOCCAL MENINGITIS\*

### A Study of Seventy-Two Cases

HARRY F. DOWLING, M.D.,† CARL C. DAUER, M.D.,‡ HARRY A. FELDMAN, M.D.,§ AND CLARENCE R. HARTMAN, M.D.¶

WASHINGTON, D. C.

BEFORE the use of the modern specific therapeutic agents, pneumococcal meningitis was almost invariably fatal. With the advent of specific serum and particularly since sulfanilamide and its derivatives have become available, a number of cases have been reported in which a relatively large proportion of patients recovered. Steele and Gottlieb,<sup>1</sup> reviewing the 115 sulfonamide-treated cases reported in the literature through June, 1940, found that recovery occurred in 60 per cent. Since June, 1940, two equally favorable reports have appeared. Rhoads and his associates<sup>2</sup> reported a recovery rate of 32 per cent among 22 patients treated with sulfapy-

ridine and specific serum; Neal and her co-workers<sup>3</sup> presented a series of 30 patients treated with sulfapyridine, of whom 10 (33 per cent) recovered.

To determine exactly how the recovery rate from this disease has been influenced by the newer therapeutic agents, we have studied all the cases of pneumococcal meningitis occurring in the District of Columbia from January 1, 1938, to October 31, 1941. It was hoped that by this method all selection of cases would be eliminated and a true picture of the mortality rate and the factors governing it could be obtained. Data on 72 cases of meningitis identified as caused by the pneumococcus were obtained from hospital and health-department records. This group includes all the cases recognized in the District of Columbia during the period mentioned. The occurrence of the cases by years is shown in Table 1. Fifty-one, or 71 per cent of all the cases, occurred during the late fall and winter months, November to 1, inclusive. This seasonal distribution is

quite similar to that of pneumococcal pneumonia. The age, sex and race of the 72 patients are shown in Table 2. The largest percentage of cases occurred in children under one year of age (31 per cent) and the next largest in adults over the age of sixty years (15 per cent). Three of the 4 patients who recovered were young adults (twenty-four, twenty-eight and thirty years of age),

14 (6 cases). Two of the first type were found in patients under two years of age, and the remaining patients were fifteen years or older. Both cases of Type 6, which is commonly encountered in children, occurred in children under two years of age. Type 16, another type found in children, was recovered from 3 infants under one year and from 3 adults. The type of pneumococcus was not determined in 9 of the 72 cases. As shown in Table 4, a history of middle-ear infection and pneumonia during or immediately preceding the development of meningitis was found in a large proportion (58 per cent) of the cases. A history of milder respiratory infections was found in an additional 21 per cent. The occurrence of otitis media was found as frequently among adults as among children. Sixty-seven of the 72 patients received one or more of the sulfonamide drugs or specific serum,

or both. In 5 cases, the meningitis appeared to develop while active treatment for pneumonia with a sulfonamide was in progress. Five patients received no serum or chemotherapy either because they died before treatment could be started or because the meningitis was not immediately recognized.

To determine whether or not therapy was adequate in each of the 67 cases, the treatment was classified as "good," "fair" or "poor." "Good" treatment with one of the sulfonamides was considered to mean: that the initial dose was 4 to 6 gm., followed by 1 gm. every four hours, in adults,

recovery ensued. "Good" treatment with specific serum was considered to mean the administration of large doses of serum by the intravenous route, with or without additional serum intrathecally and intramuscularly, begun as soon as the meningitis was recognized and repeated at frequent intervals as long as the condition of the patient

required it. The treatment in cases not meeting the above standards completely was classified as 'fair,' and that in cases in which these conditions were fulfilled only slightly was considered 'poor.'

As indicated in Table 5, 39, or 54 per cent, of the patients received what might be regarded as good treatment, 19, or 26 per cent, had fair treatment, and 9, or 13 per cent, were poorly treated. Of the 17 patients who received good treatment with

Gottlieb can easily be determined from a study of their article. Thirty of the cases in their review were published as individual case reports, and among these, 27 patients recovered. Furthermore, among the 18 cases reported in groups of two or three, there were 12 recoveries. From these figures, it is obvious that cures from this disease have heretofore been so infrequent as to lead authors to publish isolated recovered cases, whereas the

drugs alone, 5 received sulfanilamide, 9 had sulfapyridine (1 of whom recovered) and 3 had both drugs. Of those receiving good treatment with drugs and serum, 2 had sulfanilamide and serum, 14 had sulfapyridine and serum (2 of whom recovered), 3 had sulfanilamide, sulfapyridine and serum (1 of whom recovered after receiving large doses of sulfapyridine by mouth together with a small dose of sulfanilamide subcutaneously), 3 had sulfathiazole with sodium sulfapyridine and serum, 1 had sulfadiazine and serum and 1 had sulfathiazole, sulfanilamide and serum. None of the patients survived who received treatment classified as fair or poor.

One effect of therapy that has been neglected in the study of infectious diseases having a high mortality rate is the survival in patients who eventually succumb to the disease. This aspect has been considered in the last column of Table 5. Patients who received good treatment lived for an average of 7.5 days from the time meningitis was diagnosed until death. This is a considerably longer period than the average survival of 2.6 days and 2.1 days for patients given fair and poor treatment. The patients receiving no specific treatment lived an average of 1.2 days after the recognition of the disease.

#### DISCUSSION

Steele and Gottlieb,<sup>1</sup> in their review of the literature through June, 1940, covering 115 cases of pneumococcal meningitis treated with the sulfonamides, found that 69, or 60 per cent, of the patients recovered. The general experience of those interested in this disease indicates that such a recovery rate is unusually optimistic. The reason why this high figure was obtained by Steele and

bulk of unsuccessfully treated cases remains unreported.

The recovery rate was somewhat lower (45 per cent) among the remaining cases in Steele and Gottlieb's review (reported in groups of four or more). In the two large series of cases reported since the above review was made, as previously mentioned, the recovery rates were still lower, Rhoads and his associates<sup>2</sup> reporting 32 per cent recoveries among 22 patients and Neal et al.<sup>3</sup> 33 per cent among 30 patients. Thus, it is seen that the larger the number of cases in a given series the lower the recovery rate. If a large enough series of cases were studied especially if all the cases occurring in a given area were included, a figure close to the true recovery rate would be obtained. This is what we have attempted to do in the present study, with the result that we have found only 4 recoveries among 72 patients. When the patients who did not receive adequate treatment are eliminated from the study, there remain 39 patients, among whom 4, or 10 per cent, recovered. This may be considered the percentage of recoveries obtained by physicians in this locality in private and hospital practice, using the optimum treatment available at the present time.

Fourteen of the patients in the present series were treated by us personally at the Gallinger Municipal Hospital, with 3 (21 per cent) recoveries. This recovery rate probably represents the usual percentage of recoveries achieved by an active medical service interested in infectious diseases and equipped with the facilities for rapid diagnosis and treatment of pneumococcal meningitis.

If 21 per cent, or approximately one fifth, of the patients with pneumococcal meningitis recover with the best treatment available at present, what

factors appear to alter the prognosis in the individual case? A study of our cases, together with a review of those reported in the literature that have been treated with the sulfonamides, makes it evident that patients who exhibit no other focus of infection are likeliest to get well. We have observed, as Rhoads and his associates have, that when there are many cells and few organisms in the cerebrospinal fluid, the prognosis is distinctly better than when there are fewer cells and many bacteria. A higher death rate occurs in the very young and the very old, as in most infectious diseases. The type of infecting pneumococcus seems to have no effect on the prognosis. We could find no correlation between the day on which treatment was begun and the outcome of the case. However, since the diagnosis was not always made promptly and since it was difficult to determine the exact onset of the disease in many cases, these data are not very reliable.

Our figures indicate that sulfapyridine is superior to sulfanilamide, since all 4 recoveries occurred among the 41 patients treated with sulfapyridine with and without serum, and none of the 30 patients treated with sulfanilamide, alone or with serum, recovered. The few patients treated with sulfathiazole and the 1 patient treated with sulfadiazine died. It is quite likely that Steele and Gottlieb's finding that a greater percentage of patients recovered after receiving sulfanilamide than after the administration of sulfapyridine was due to the fact that sulfanilamide was the first of the drugs to be used and any recovery was worth reporting. By the time sulfapyridine was introduced, recovery from pneumococcal meningitis was no longer rare, and many cases of recovery were undoubtedly not reported.

No conclusion can be drawn from our cases concerning the efficacy of specific serum in addition to the sulfonamides. Three of our patients who were children, occurring in 1 case of Type 1 and 2 cases of Type 2, were recovered and from 3 cases of Type 2 was not determined.

As shown in the preceding table, infection preceded treatment in 1 case. A higher percentage was found in a series of 100 cases. A higher percentage was found in a series of 100 cases.

Sixty-seven cases more of the

recovered received the combined therapy, whereas the fourth received sulfapyridine alone. Until more evidence is available, we believe that serum and sulfapyridine or sulfadiazine should be used in combination.

### SUMMARY

An analysis of all the cases of pneumococcal meningitis, 72 in number, occurring in the District of Columbia between January 1, 1938, and October 31, 1941, is presented.

Only 4 of these patients survived, all of whom were classified among the group of 39 patients who received good treatment with the sulfonamide drugs or specific serum or both. Among the 19 patients who were given only fair treatment, the 9 patients who received poor treatment and the 5 patients who received no specific treatment of any kind, there were no recoveries.

Among the fatal cases, those receiving good treatment survived an average of 7.5 days after the meningitis was diagnosed, and those who were given fair, poor or no treatment survived an average of 2.6, 2.1 and 1.2 days, respectively.

With the best treatment at our disposal today, on an active medical service interested in infectious diseases and equipped with facilities for rapid diagnosis and treatment, the mortality rate from pneumococcal meningitis is about 80 per cent.

The factors influencing the prognosis and treatment of pneumococcal meningitis are discussed.

THE RECLASSIFICATION OF REPORTED CASES OF  
TUBERCULOSIS IN MASSACHUSETTS

## Present Report

Edward J. Welch, M.D., and Peter Zuck, M.D.

242

SINCE 1917, pulmonary tuberculosis has been by law a reportable communicable disease in Massachusetts. All other forms of tuberculosis have, since that time, been added to the list of reportable diseases. With the intensification of the legal requirements, there came increased attention on the part of private physicians, local health agencies and the Massachusetts Department of Public Health in finding, treating and following these cases. Altogether, 209,892 cases have been reported in Massachusetts from 1917 to 1940. The percentage of the actual cases that this figure represents is not known. Although the majority of physicians have been conscientious in reporting their cases, others have been lax in this duty. Often, to satisfy a patient's desire for secrecy, reporting of the case has been omitted, the health authorities have had no opportunity to guide the patient, if treatment is neglected, and no search for contact cases has been made. Fortunately, as tuberculosis has come more into the open and as hopeful programs of prevention and treatment have developed, this type of neglect has diminished. Today, the chief sources of error by the physician in failing to report cases appear to be missed diagnoses and lapses of memory.

The duties of the practicing physician are few and simple to report each case on the proper form to the local board of health, to arrange for treatment and continued observation of the patient in competent hands, with public health supervision or hospitalization in a sanatorium for the case with positive sputum, and to arrange or to allow the public health nurse to arrange for the examination of contacts.

A more frequent resort to roentgenograms of the chest, to thorough sputum analysis for tubercle bacilli (including the more sensitive methods if smears are negative) and, finally, to consultation in suspected cases will prevent missed diagnoses in pulmonary cases. In extrapulmonary cases, which are usually recognized with less difficulty, doubt should also lead to consultation.

The duties of the local boards of health in reported cases are as follows: the physician in charge of the case should be consulted and a

been the main factor in the progress of the case as  
 given by the medical expert, and the patient  
 negligence in the matter of the doctor's visit to the  
 hospital and the doctor's treatment, and the  
 patient's failure to take proper treatment and to  
 have regular checkups by his physician or im-  
 proper treatment by his doctor should be investigated  
 and a report should be made to the examining  
 committee and the committee of the physician in  
 which the above are need for this.

In 1938, the Division of Tuberculosis of the Massachusetts Department of Public Health first undertook to investigate and advise local boards of health regarding their lists of reported cases. It was found that in most localities these lists had grown to such a high figure that it was beyond the ability of the local nurse to follow every case. Many lists had not even been corrected for deaths, removals to other towns, unlocated cases and so forth. It was believed that it would be possible to revise these lists by a reclassification of all reported cases and by the establishment of new lists for the cases still in need of observation. This revision was first carried out during the summer months when the personnel of the state school clinics was available to do the work. Since July 1939, the work has been carried on throughout the year aided by a grant from the United States Public Health Service providing for full time personnel and necessary equipment. It has been possible, as a result of this study, to reduce the lists of cases requiring further observation to a workable number. It is hoped that this will stimulate greater activity by the boards of health in following tuberculous patients and their families.

The reclassification has been carried out thus far in one hundred and thirty cities and towns of Massachusetts, in most of which clinics have been held following a preliminary exclusion of all deaths removals to other places and unlocated cases. Cases having recent roentgenograms of the chest—that is within twelve months—available in local sanatoriums were first reviewed there and if possible, were reclassified without being invited to the clinic. A home visit was made in each of the remaining cases by the local public health nurse, and the patient was asked to attend the clinic. Of those refusing to come either local

Assistant in Medicine Boston University School of Medicine  
 Physician in Chief Channing Home Boston  
 Chief of Clinics Division of Tuberculosis Massachusetts Department  
 of Public Health

histories or x-ray films were reviewed, and the cases thus reclassified.

As the patients come to the clinic, complete medical histories of their disease are recorded, and physical, x-ray and sputum examinations made. The cases were finally classified as follows.

*Active list.* This group, which requires further study, includes all pulmonary cases showing active disease by clinical findings, by x-ray examination or by positive sputum; all cases in sanatoriums at the time of reclassification; cases thought to be inactive clinically but not yet followed long enough to be unmistakably so; all cases under collapse therapy (including thoracoplasty cases), regardless of health or x-ray findings; and extrapulmonary patients in sanatoriums who have discharges or clinically active disease.

*Inactive list.* This group, which does not require further follow-up, comprises inactive

own merits. It is impossible to establish fixed rules for such a procedure. Ideally, every case of pulmonary tuberculosis would be followed by periodic checkup into old age. With the scant funds and limited personnel usually assigned to tuberculosis work in most communities, such a program is impossible, and the number of cases to be followed must be kept at a workable figure. Although it is apparent that almost any case of pulmonary tuberculosis may become reactivated, cases with a long history of arrested disease are less apt to do so than those known to have had recent activity. Arbitrarily, then, in a reclassification of this sort, the latter group constitutes the bulk of cases kept for observation after an initial list of cases with active disease has been established. Emphasis falls, of course, on the pulmonary group, in which the real menace to the public health lurks. In all cities and towns where we have conducted clinics, we have attempted to

TABLE 1. *Summary of Findings in 2286 Reclassified Cases.*

Totals	2286	1211 (53%)	1013	44	18

cases of pulmonary tuberculosis in which the patient has been symptom free for several years and in which there is x-ray evidence of healed fibrotic or calcified lesions, or negative x-ray films and negative sputum—in many cases, films taken over a period of eight to ten years are available for determination of the status of the lesions; pulmonary cases proved to be non-tuberculous, including bronchiectasis, asthma and cardiac disease; extrapulmonary cases without symptoms, physical signs or discharges, and having a negative x-ray film of the chest; and childhood-type cases in patients past school age.

*Contact observation.* This group includes reported cases without present evidence of tuberculosis but kept for observation because of contact history.

*School clinic.* This group consisted of primary (childhood-type) cases of school age, kept for observation by the school clinic. (It should be noted that primary tuberculosis is no longer a reportable disease in Massachusetts.)

The reclassification of the individual case is a difficult problem, each case being decided on its

emphasize the value of control of proved cases. The follow-up of negative contacts (especially in children under ten years of age) is overdone in many communities, is of secondary importance and should be sacrificed when economy of effort is required.

At the end of the reclassification in each city or town, every patient who comes to the clinic is sent a letter stating the reclassification. Patients whose names are placed on the inactive list are advised to have an annual physical examination by their own physicians and to seek advice and treatment at once if they should ever have a return of symptoms.

This preliminary report is based on three cities (Fall River, Brockton and Worcester) whose original lists of reported cases totaled 3215. After the initial check, we were able to remove 929 cases because of deaths, or removals to other cities or because they could not be located in the cities. Of the 2286 cases left for reclassification, Table 1 presents the findings. Perhaps the most interesting finding is that only 22 per cent of the patients who reported to the clinic for examination were thought to require further observation. This figure is indicative of the effective reductions made

in the local lists of reported cases when we were successful in obtaining the co-operation of the patients and in getting them examined. Out of 3215 reported cases listed, only 1211, or 38 per cent, were retained on the active list, an additional 62 being kept for school clinic or contact observation.

Similar reductions are being effected in other cities and towns, and it is believed that the work of the local boards of health is being satisfactorily cut to a point where it can be handled in an easier

manner than has hitherto been possible. It is planned to report a further analysis of the material available from these studies at a later date, breaking down the statistics for pulmonary and extrapulmonary cases.

#### SUMMARY

The methods for and the results of the reclassification of reported cases of tuberculosis in three cities of Massachusetts are outlined and discussed.

## CLINICAL NOTE

### PERIPHERAL NEURITIS FOLLOWING THE ADMINISTRATION OF A GLUCOSE SULFAPYRIDINE COMPOUND\*

SAMUEL J. SUGAR, M.D.†

WASHINGTON, D. C.

**A**MONG the toxic reactions that follow the administration of sulfanilamide and its derivatives, involvement of the peripheral nerves is one of the least frequent.<sup>1</sup> This complication has been reported by various authors as occurring after the use of sulfanilamide,<sup>2,3</sup> sulfathiazole,<sup>4</sup> sulfamethylthiazole<sup>5-7</sup> and disulfanilamide.<sup>8,9</sup> Apparently, only 2 cases of peripheral neuritis after sulfapyridine have been mentioned in the literature. The first of these<sup>10</sup> is mentioned only briefly and is not fully described. The other case<sup>11</sup> was observed following the use of antimeningococcal serum and sulfapyridine, and since other signs of serum sickness appeared, the neuritis may have been due to the serum as well as to the drug.

While investigating, in a series of 60 patients with pneumonia, the therapeutic effects of glucose sulfapyridine, a crystalline compound synthesized by Dr. Lloyd D. Felton, of the National Institute of Health, I observed a case of peripheral neuritis that was apparently caused by the sulfapyridine portion of the compound. The preparation used was simply a condensation product of the aldehyde group of glucose with the amine group of the aminobenzene radical of the sulfapyridine. Analysis showed it to be a combination of one molecule of glucose with one molecule of sulfapyridine that thus required double the dosage of regular sulfapyridine to achieve similar drug intake.

#### CASE REPORT

H. G., a 23-year-old Negro, was admitted to the George Washington Medical Division of Gallinger Municipal Hospital on December 22, 1940. He had developed a cold on December 16 and the following day had noticed fever and pain in the right chest. On December 18, he became dyspneic and had a severe chill. Cough was productive of "prune-juice" sputum. There was no history of excessive indulgence in alcohol, of the use of drugs, of avitaminosis or of any neurologic disease.

Examination showed a well-developed and well-nourished young colored man who appeared acutely ill, with moderate dyspnea accompanied by an expiratory grunt. Physical examination revealed consolidation involving the upper lobe of the right lung; this was confirmed by a roentgenogram. The temperature was 102.4°F., the pulse 104, and the respirations 32. Sputum typing and a culture of the blood taken on December 24 both revealed Type 8 pneumococci. The white-cell count was 19,300, with 66 per cent polymorphonuclears, 23 per cent band forms; 3 per cent young forms and 8 per cent lymphocytes. The red-cell count was 4,520,000, with 78 per cent hemoglobin.

An initial dose of 8.0 gm. of glucose sulfapyridine was given, followed by 2 gm. every 4 hours; 1 gm. of sulfapyridine was substituted for each of two doses of glucose sulfapyridine during the 2nd day of treatment. Blood sulfapyridine levels of the drug reached 4.4 mg. per 100 cc. of free and 10.9 mg. of total sulfapyridine, 4 hours after the initial dose. Thereafter, the levels remained between 1.1 and 2.3 mg. per 100 cc. of free and between 2.2 and 5.4 mg. of total sulfapyridine, except for one rise 28 hours after the beginning of treatment to 5.0 mg. per 100 cc. free and 10.9 mg. of total sulfapyridine. The drug was discontinued on December 27 (the 6th day of treatment), after a total of 50 gm. of glucose sulfapyridine and 2 gm. of sulfapyridine had been given.

On the following day, the patient complained of numbness and tingling and difficulty in flexing the right 4th and 5th fingers. Examination revealed marked hypesthesia to pinprick over the 5th finger and the medial half of the 4th finger and over the ulnar half of the palm and dorsum as far as the wrist. There was no abnormality in ability to distinguish vibration, temperature or position. The patient was unable to distinguish the feel of wetness of water over the affected area. A diagnosis of peripheral neuritis along the distribution of the ulnar nerve was made. The symptoms and signs continued for 2 days, and the patient then left the hospital against advice. When he returned for observation 3 weeks later, all the abnormal signs and symptoms had disappeared.

\*From the George Washington Medical Division, Gallinger Municipal Hospital, Washington, D. C.

†Resident in medicine, Gallinger Municipal Hospital

Although I have seen no other case of peripheral neuritis among patients with pneumonia receiving sulfapyridine or glucose sulfapyridine, I believe that the evidence is unequivocal that the drug was the cause in the case reported. Except for a small amount of codeine and elixir of terpin hydrate, the patient received, during his hospital stay, only the glucose sulfapyridine and the sulfapyridine.

Finland and his coworkers<sup>12</sup> and Ensworth and his associates,<sup>13</sup> investigating a different glucose sulfapyridine compound, found that after absorption from the gastrointestinal tract, the glucose and sulfapyridine were separated. My own experience with the compound used in the present case coincides with this conclusion. So far as therapeutic and toxic results are concerned, sulfapyridine is therefore the only drug involved.

As the evidence accumulates, it is becoming increasingly likely that the conclusion will eventually be reached that most of the toxic manifestations that occur following any one of these drugs may sometimes occur following the use of others in the group. The variations in toxic complications following the different sulfones are therefore largely quantitative. Peripheral neuritis seems to fit into this general scheme. On the evidence of clinical reports up to the present, such neuritis is most frequent following the use of sulfamethylthiazole and disulfanilamide, is fairly often observed after the administration of sulfanilamide, and is rare following sulfathiazole. The case re-

ported suggests that this complication, although it is very rare indeed, occasionally follows the use of sulfapyridine.

### SUMMARY

A case of peripheral neuritis, with recovery, that occurred after the administration of 50 gm. of glucose sulfapyridine and 2 gm. of sulfapyridine is reported.

## MEDICAL PROGRESS

## OPHTHALMOLOGY

J HERBERT WAITE, M.D.\*

BOSTON

IT is my opinion that the work of greatest ophthalmologic interest and promise during recent years includes clinical and laboratory studies in chemotherapy and vitamin therapy, and in the pathogenesis of cataract and uveitis, and attempts to master corneal transplantation. Chemotherapy and vitamin therapy are accomplishing feats in ophthalmology that were formerly not attainable. Intensive search for the causes of cataract and uveitis—major problems in ophthalmology—has already been too long delayed. Successfully accomplished corneal grafts are salvaging the eyesight of patients heretofore considered incurably blind.

## CHEMOTHERAPY

Chinn and Bellows,<sup>1</sup> vanDyke et al.,<sup>2</sup> Spink and Hansen,<sup>3</sup> Long and Bliss,<sup>4</sup> Hill,<sup>5</sup> Rammelkamp and Keefer,<sup>6</sup> Sadusk, Blake and Seymour<sup>7</sup> and others have pioneered the way for sulfonamide therapy (sulfanilamide, sulfapyridine, sulfathiazole and sulfadiazine), with especial reference to solubility, to selective action on invading organisms, to concentration and maintenance levels in blood and tissue, to methods of increasing concentration of the drugs in avascular tissue, and to host idiosyncrasy.

The extent to which the sulfonamides reach the tissues of the eye was studied in dogs by Bellows and Chinn,<sup>8</sup> who found that the maximum drug concentration in blood and eye was reached from four to six hours after administration by stomach tube. On removal of the eyes four hours after uniform dose by stomach, and on analysis of blood and the tissues and fluids of the eye, these workers found the following distribution:

TISSUE	SULFANILAMIDE mg /100 cc or gm	SULFAPYRIDINE mg /100 cc or gm	SULFATHIAZOLE mg /100 cc or gm
Blood	18.0	6.1	7.4
Lens	2.7	1.1	0.0
Aqueous	10.9	4.9	0.9
Vitreous	8.4	5.8	2.0
Cornea	13.4	6.6	4.9
Choroid and retina	15.2	6.3	

From these observations, the authors believe that sulfathiazole is less effective in controlling intra-

ocular infection than other sulfa preparations. Scheie and Souders<sup>9</sup> reported similar findings in cats.

Using rabbits, Liebman and Newman<sup>10</sup> found it possible to increase the concentration of the sulfonamides in the aqueous by 50 per cent through repeated paracenteses, the first being made three hours after drug administration, and thereafter at thirty-minute intervals, with comparative results as follows:

DRUG	PRIMARY CONTENT OF AQUEOUS % blood conc.	SECONDARY CONTENT OF AQUEOUS % blood conc.
Sulfanilamide	67	96
Sulfapyridine	64	98
Sulfathiazole	17	41
Sulfadiazine	55	102

The increase in concentration in the aqueous is explained by the fact that the secondary fluid is a transudation from capillary blood; such an increase gives the clinician a clue to a more effective method of combating intraocular inflammation.

Caution to the point of timidity on the part of ophthalmologists has led to disappointing results in the early clinical use of sulfa drugs to control eye infections. The maintenance of blood levels of 1 to 3 mg. per 100 cc., with a correspondingly lower level in the avascular tissues of the eye, is apparently not sufficient to curb infection in ocular tissues. Mild eye infections require blood concentrations of 3 to 5 mg. per 100 cc. for five to seven days, and severe infections require levels of 6 to 12 mg. per 100 cc. for a week, as outlined by Guyton and Woods<sup>11</sup> after a careful study of 104 patients. The concentration of the drug in the blood should not exceed 20 mg. per 100 cc. on account of possible toxic effects, and effective concentration in the ocular fluids and tissues may be gained through repeated paracenteses at the peak of blood concentration.

It appears to be the consensus among careful clinicians that sulfanilamide acts more effectively for streptococcus; sulfapyridine for influenza (Koch-Weeks) bacillus, pneumococcus and meningococcus; and sulfathiazole for infections of the eye and adnexa caused by the gonococcus and

Reprints of articles in this series are not available for distribution, but the articles will be published in book form. The current volume is *Medical Progress Annual, 1940* (Springfield, Illinois: Charles C. Thomas Company, 1941) \$4.00.

\*Lecturer in ophthalmology, Harvard Medical School consultant in ophthalmology, New England Deaconess Hospital and Massachusetts Eye and Ear Infirmary.

gram-negative bacilli. *Staphylococcus*, killed in vitro by sulfathiazole in a concentration of 100 mg. per 100 cc., does not succumb to any sulfonamide level that can safely be administered to patients. Sulfonamide therapy has not proved effective in uveitis, sympathetic ophthalmia (Gamble<sup>12</sup>) or herpetic virus infections of the eyeball.

Clinical success, sometimes verging on the dramatic, has attended sulfonamide therapy in three virus diseases that consistently show basophilic heterogeneous inclusion bodies: trachoma, inclusion blennorrhea and lymphogranuloma venereum. A fourth basophilic inclusion virus, psittacosis, theoretically should succumb to sulfonamide therapy. Other virus diseases, nonvulnerable to these drugs, curiously exhibit acidophilic homogeneous inclusion bodies, according to Thygeson.<sup>13</sup> If one accepts the evidence of Julianelle et al.,<sup>14</sup> Loe<sup>15</sup> and Thygeson,<sup>16</sup> one may believe that the trachoma virus resists local applications of sulfanilamide, or blood levels below 3 to 5 mg. per 100 cc., but that it is cured by the maintenance for one week to ten days of blood levels approximating 10 mg. per 100 cc. Inclusion blennorrhea, hitherto a stubborn disease active for months under previous therapy, now, according to Thygeson,<sup>16</sup> yields in several weeks to sulfanilamide at blood levels of 3 to 5 mg. per 100 cc. Macnie<sup>17</sup> discusses the value of sulfanilamide therapy in lymphogranuloma venereum over all other known therapeutic agents.

Every patient receiving these drugs should have a daily water intake of 2500 cc., repeated blood analyses to check retention of the drug in case of renal damage, and alertness on the part of the physician for appearance of signs of idiosyncrasy. Idiosyncrasy may express itself as acidosis, nausea and vomiting, cyanosis, hematuria, skin rash, fever, hepatitis, acute hemolytic anemia or leukopenia occasionally going on to agranulocytosis and fatal outcome. The discontinuation of the drug should be guided by clinical judgment based on experience.

Sulfonamide idiosyncrasy may express itself in the visual mechanism, showing in the conjunctiva as injection and in the crystalline lens as a transitory myopia. Similar transitory refractive changes are observed in diabetes, jaundice, arsphenamine therapy, alkalosis and dehydration (Granström<sup>18</sup>). In the patient toxic from sulfonamide drugs, shifting of the refraction to myopia, frequently not observed by the patient, may evade the watchful eye of the physician unless carefully sought. Such a shift has been reported by Berns,<sup>19</sup> Spellberg,<sup>20</sup> Gailey,<sup>21</sup> Missiroli,<sup>22</sup> Blankstein,<sup>23</sup> Friedman<sup>24</sup> and Hornbogen.<sup>25</sup>

## VITAMIN THERAPY

Long misinterpreted and little understood, vitamin deficiencies such as night blindness, beriberi, pellagra, rickets, scurvy and sprue are finding explanation in the lack of sufficient vitamins in food, faulty absorption from the bowel, or faulty utilization by the cells of the body. In 1911, Casimir Funk first gave a name to the vital principle, and in 1913 Vedder and Williams<sup>26</sup> first gave proof of the reality of vitamin deficiency. Until chemical structure became known, vitamins had to parade under alphabetical aliases, the letters A to K having been given to clinically recognized vitamins, and the remaining letters to the hypothetical ones. What was formerly known as vitamin B has recently been resolved into at least twelve components, each with different qualities. Therefore, interpretation of vitamin action in the past has been chaotic, and it is just now emerging from the umbra of uncertainty as vitamin principles are synthesized, labeled with chemically descriptive names, and studied separately with respect to physiologic action, synergism and toxicity. Important examples are:

OLD NAME	NEW NAME	ACTION
A	Precursor-carotene	Antinyctalopic and antixerophthalmic
B <sub>1</sub>	Thiamine	Antineuritic
B <sub>2</sub>	Riboflavin	Promotes cell respiration
Nicotinic acid	Niacin	Antipellagrous
C	Ascorbic acid	Antiscorbutic
D	Radiated ergosterol	Antirachitic
E	Alpha tocopherol	Prevents sterility
K	Naphthoquinone	Antihemorrhagic

Salter<sup>27</sup> gives an excellent review of vitamin chemistry and current methods of assay in blood, urine and tissues. Outside the body, some vitamins are decomposed by light, and others are lost in food processing, packing and pasteurization; within the body, there is loss by abnormal excretion in colitis and polyuria, by partial destruction in achlorhydria and liver dysfunction, and by faulty absorption in steatorrhea or in too liberal use of mineral oil. Researches in vitamin chemistry, utilization and fate in the human being are awaited with keen interest by every clinician who wishes to bring his patients factual rather than empirical aid in vitamin therapy.

The advent of vitamin therapy, empirical though it has been, has brought to ophthalmology certain benefits. Yudkin<sup>28</sup> commits himself to the belief, shared by other clinicians, that an adequate vitamin A intake has reduced the incidence of phlyc-

tenuis keratoconjunctivitis, hordeol, and night blindness. Thiamine deficiency has been implicated in ophthalmoplegia and in retinobulbar neuritis. Rosacea conjunctivitis and keratitis, with stubborn and recurrent ulceration of the cornea, have been attributed to riboflavin deficiency. Thiamine and riboflavin, along with glutathione, ascorbic acid and nicotinic acid amide, are fundamental to cell respiration. They are not stored in the body, and they must be replenished daily. According to Booher,<sup>9</sup> the inadequacy of riboflavin leads to cell asphyxiation, expressing itself in the adolescent as retarded growth and in the adult as changes in the skin, changes in the central nervous system and changes in the cornea, conjunctiva and crystalline lens of the eye. The minimum requirement of riboflavin for human beings is 3 mg daily,<sup>10</sup> and it is best obtained from cow's milk, which, during the first month of lactation, contains 54 mg per quart.<sup>11</sup>

Crude thiamine and riboflavin must be converted into the phosphoric acid ester before they are acceptable for cellular oxidation and phosphorylation is thought to take place in the liver.<sup>12</sup> Carboxylase, the phosphoric acid ester of thiamine, in normal amounts acts as an antineuritic, in subnormal amounts, it arrests the oxidation of carbohydrate at the pyruvic acid stage and promotes the development of polyneuritis in the presence of toxic agents. The phosphoric acid ester of riboflavin in normal amounts, according to Veahey,<sup>13</sup> promotes cell respiration, and its absence, as shown by Bessey and Wolbach,<sup>14</sup> leads to more degenerative changes and attempts to repair by vascularization. Riboflavin does not survive gastric achlorhydria and the alkali of the duodenum. The Snell-Strong method of assay for riboflavin, although not sufficiently accurate for reliable estimate of riboflavin in vivo, capitalizes the fact that *Lactobacillus casei* *sp. nov.* cannot synthesize riboflavin and yet cannot survive without it.

Other vitamin B components — synergists and less well understood — are niacin (nicotinic acid), pantothenic acid, biotin and para-aminobenzoic acid. Deficiency of niacin leads to pellagra, with photosensitive dermatitis, keratitis and corneal ulceration, all of which are relieved by therapy with nicotinic acid amide. Georgy and Eckhardt<sup>15</sup> report that lack of pantothenic acid and biotin leads to blanching of the eyelashes and hair, and later to keratitis. Ansbacher<sup>16</sup> found that para-aminobenzoic acid inhibits the bacteriocidal action of sulfonamide.

Johnson and Eckhardt<sup>17</sup> demonstrated the healing and remission of vascularization of the cornea when the riboflavin deficit is made up. The following year, Johnson<sup>18</sup> established the chemical re-

lationship between the dermatitis conjunctivitis and keratitis of rosacea and riboflavin deficiency by rapid amelioration of signs by means of riboflavin therapy. He recommends intravenous injections for several days of 2 mg riboflavin, and concomitant oral administration of riboflavin with hydrochloric acid, since many patients with rosacea exhibit achlorhydria. After the course of treatment is completed, Johnson continues a daily riboflavin rich diet containing milk, liver and egg white. Beams, Free and Glenn<sup>19</sup> substantiate the excellent results of Johnson in the relief of rosacea keratitis through riboflavin therapy.

#### PATHOGENESIS OF CATARACT

The term *cataract*, derived when oculists were ocellists was then used to denote vision obstructed by advanced degeneration of the lens. Now, with refinements of the biomicroscope, gross covering over 100 types of lens blemishes, gross and microscopic, the same blanket term continues to be used indiscriminately, and thus to constitute one of the most flexible and most fearful words in the medical vocabulary. At the caprice of the oculist any lens blemish may be designated 'cataract', whether it is the stationary and microscopic foveal blemish within the nucleus that never obstructs vision, or the equatorial blemish of adolescence that seldom obstructs vision, or the senile radial blemish which may or may not progress after long periods of status quo or the intumescent degeneration of the entire lens with rapid decline in useful vision. For intelligent understanding between oculist, physician and hyman, the term 'cataract' should be replaced by an exact nomenclature for lens abnormalities that takes into account the lens architecture and the causation and the ultimate fate of lens abnormalities.

The crystalline lens is an island of epithelium bathed in aqueous that is a dihyalite from capillary blood, devoid of nerve or direct blood supply, surrounded by a semipermeable capsule, and provided with its own oxidation mechanism and its own protective measures for the maintenance of transparency. Its respiratory quotient is unity, its cellular oxidation and metabolism are negotiated by glutathione, ascorbic acid and riboflavin, and its water absorption is counteracted by the cholesterol content. No single theory of cataract causation encompasses or explains all known types of cataract.

The role of calcium and calcium in cataract production has been investigated by Meemann<sup>20</sup> and by von Birr.<sup>21</sup> Using the Birkler<sup>22</sup> technique for survival of the rabbit lens in vitro, von Birr demonstrated that lens changes do not follow low calcium content unless a cataractogenic substance

an unidentified protein molecule derived from hemolyzed blood, is also present. In his opinion, lens changes do not develop collaterally with human or rat rickets unless the blood calcium falls below 7 mg. per 100 cc., and unless tetany is present. In rickets, tetany is precipitated by the addition of a diet rich in phosphates, which are present in cow's milk. If tetany is transient, the lens blemish becomes zonular, and if tetany is persistent, the blemish becomes total.

Bellows and Chinn,<sup>43</sup> in fifteen papers, the last three of which were published during 1941, express the belief that the crystalline lens is a delicate osmometer, and that cataract is fundamentally the result of osmotic derangement. Paper XIII<sup>44</sup> concerns the two osmotic barriers that separate the blood from the lens cell-fiber system, and the constant interchange through these membranes of water, foodstuffs, oxygen and waste products. Paper XIV<sup>45</sup> deals with injury and altered permeability of the lens capsule and its epithelium. Paper XV<sup>46</sup> describes the swelling of the isolated lens as related to tonicity of the surrounding medium, to ionic content and hydrogen ion concentration, to temperature and to other factors.

Salit,<sup>47</sup> after a study of two hundred and fifty-nine cataractous and sclerosed lenses, removed in capsule, with reference to lipid and cholesterol content, adduces evidence that cholesterol has much to do with the water content of the lens, and that the intumescent stage of cataract is traversed by lenses that are low in the cholesterol-lipid ratio but high in total lipids.

The part played by vitamins in cataract production is suggested in the very low ascorbic acid and riboflavin content of cataractous lenses, and in the fact that the addition of adequate amounts of vitamin D to the diet in rickets and tetany prevents cataract formation.

#### PATHOGENESIS OF UVEITIS

Inflammations of the iris, ciliary body or choroid are frequently recurrent, and each attack may be accompanied by complications that endanger sight, such as glaucoma, cataract, hypotension and heavy vitreous opacities. To curb each attack and to prevent recurrences, it has become the accepted practice to make a detailed search for potential sources of uveitis throughout the body. Seldom is it possible to fulfill the postulates of Koch with respect to uveitis, and it is often impossible to demonstrate anywhere in the body what might be considered an adequate focus.

Duggan<sup>48</sup> has added the concept of tissue anoxia as a potential cause of uveitis, and he hypothesizes release of histamine locally, dilation of the uveal capillary bed, and local tissue anoxia, inflam-

mation and necrosis. He claims to be able to control this vicious circle by active vasodilator therapy, combining daily intravenous injections of 0.1 gm. of sodium nitrite with oral administration daily for two weeks of 15 to 30 mg. of erythrityl tetranitrate. Duggan also speculates on the value of a histamine ferment to destroy the noxious agent.

The search for focus applies to the paranasal sinuses, the teeth, the tonsils, the chest, the abdomen and the pelvis for the presence of pyogenic and nonpyogenic bacterial infection, and for evidence of syphilis, tuberculosis, leprosy, brucellosis and virus infection. Also, one searches for protozoan and animal parasites, which directly or through their toxins have been named as potential sources of uveitis; such parasites are *Plasmodium malariae*, *Endamoeba histolytica*, *Treponema pertenue* and *Trichinella spiralis*. Finally, one searches for allergy, particularly for the allergy from bacterial protein, tuberculo-protein and brucellar protein. The relation between arthritis and uveitis has long been recognized clinically.

Concurrence does not prove pathogenesis. From the clinical standpoint, improvement of the ocular inflammation and avoidance of ocular complications and of recurrences are the goals sought. From the standpoint of true etiology, one must be able to recover the causative agent, and to reproduce the same disease in a healthy eye. Until this requirement has been met, the pathogenesis of uveitis cannot be considered solved.

After a thoroughgoing clinical study of 244 house patients with uveitis at the Johns Hopkins Hospital, Guyton and Woods,<sup>49</sup> by clinical criteria, have allocated "causes" as follows: tuberculosis, 54 per cent; syphilis, 19 per cent; focal infection, 14 per cent; gonococcal infection, 4 per cent; and miscellaneous, 9 per cent. They do not claim that they are able to demonstrate actual micro-organisms within the infected tissues, a feat seldom accomplished in uveitis by the most meticulous staining or cultural methods. They do not report vitamin assay or virus cultures as part of their study.

#### CORNEAL TRANSPLANTATION

Nizetic<sup>50</sup> has reviewed a century of mostly unsuccessful effort to engraft healthy and clear cornea on an eye that lacks a transparent cornea, and he has outlined the contributions made by various workers.

Castroviejo<sup>51</sup> is beginning to obtain gratifying results after having performed four hundred keratoplasties on animal eyes and over two hundred keratoplasties on human eyes. His chief difficulty at present seems to be lack of donor material, rather than lack of recipients or technical difficulty

in transferring the graft. Using a double-blinded knife with blades set 4 mm. apart, the operator outlines in donor and recipient corneas a 4 mm. square, cutting through two thirds of the corneal thickness. Having used fluorescein to mark the initial incision thus made, the operator completes the incision through the cornea on one side of the square with a narrow 45°-angle keratome, cutting through the posterior third of the thickness of the cornea on a bevel. The other three sides of the square are cut through on a bevel by special scissors. Thus, the graft, 1 mm. thick and 4 mm. on each of its four sides, shows in the anterior two thirds of its thickness perpendicular sides, and in the posterior third of its thickness a 20° beveling, which prevents the graft from slipping into the anterior chamber. Formerly, the graft was held in position by a superimposed conjunctival flap. Now, the graft is held in place by a well-designed suture, which is looped over the graft from the insertion points in the adjacent peripheral cornea.

To meet the need for sufficient donor material, Castroviejo<sup>52</sup> has worked out a satisfactory method for preservation of corneal tissue in a moist chamber kept at 2°C. Thus, a cornea may be preserved for nine days free from demonstrable histologic changes. To obtain the best results, donor material is used, if possible, at once or within twenty-four hours of removal from the donor. If necessary, the operator may take four grafts of proper size outlined above from one donor cornea.

Following the lead of European workers, — notably Salzer and Magitot, — Wiener and Rosenbaum<sup>53</sup> have experimented with chemically fixed corneas from dogs and rabbits as donor material. From nine formalinized donor corneas, they report eight takes. From eight donor corneas, fixed with Ptunkowitsch's solution, they report seven takes. Healing is very slow with chemically fixed grafts, because the stroma of the graft must be replaced by the fixed cells of the recipient's cornea, and the epithelium and endothelium of the graft must be reformed from those of the recipient.

If necessary, the operator may take four grafts of proper size outlined above from one donor cornea.
- 53 Wiener M. and Rosenbaum S. Following the lead of European workers, — notably Salzer and Magitot, — Wiener and Rosenbaum have experimented with chemically fixed corneas from dogs and rabbits as donor material. From nine formalinized donor corneas, they report eight takes. From eight donor corneas, fixed with Ptunkowitsch's solution, they report seven takes. Healing is very slow with chemically fixed grafts, because the stroma of the graft must be replaced by the fixed cells of the recipient's cornea, and the epithelium and endothelium of the graft must be reformed from those of the recipient.

## MASSACHUSETTS MEDICAL SOCIETY

## PROCEEDINGS OF THE COUNCIL

Annual Meeting, May 25 and 26, 1942

THE annual meeting of the Council of the Massachusetts Medical Society was called to order at 7:00 p.m. in the Georgian Room of the Hotel Statler, Boston, on Monday, May 25, 1942, by the president, Dr. Frank R. Ober, Suffolk; 226 councilors were present (Appendix No. 1).

The Secretary presented the record of the special meeting held on April 15, 1942, as published in the *New England Journal of Medicine*, issue of May 14, 1942. This record was approved by the Council on a motion by Dr. Walter G. Phippen, Essex South, and a second by Dr. W. Jason Mixer, Suffolk.

The following nominating councilors answered the roll call by the Secretary: W. D. Kinney, Barnstable; P. J. Sullivan, Berkshire; W. H. Allen, Bristol North; E. F. Cody, Bristol South; G. L. Richardson, Essex North; Bernard Appel, Essex South; A. G. Rice, Hampden; L. B. Pond, Hampshire; R. R. Stratton, Middlesex East; W. H. Sherman, Middlesex North; Dwight O'Hara, Middlesex South; D. D. Scannell, Norfolk; D. B. Reardon, Norfolk South; W. H. Pulsifer, Plymouth; W. B. Breed, Suffolk; R. P. Watkins, Worcester; and B. P. Sweeney, Worcester North. W. J. Pelletier, alternate member, responded for Franklin. The Committee on Nominations, so constituted, retired to deliberate.

Dr. J. Harper Blaisdell, Middlesex East, moved that if and when the annual meeting of the Council recesses it be until Tuesday, May 26, 1942, at the end of the Annual Discourse, which concludes the annual meeting of the Society. This motion was seconded by Dr. William M. Collins, Middlesex North. Dr. Blaisdell explained that this motion was offered for the purpose of giving the annual meeting of the Council the opportunity to fulfill its obligations when and if the annual meeting of the Society adopted the by-laws which were to be presented to it. This motion was unanimously adopted by the Council.

## REPORTS OF STANDING COMMITTEES

*Executive Committee*

The Secretary in presenting the report (Appendix No. 2) said that this committee had held five meetings since the stated meeting of the Council in February, 1942, and that two of these meetings were by way of hearings which were granted to the Committee on By-Laws, together with the

members of those committees likely to be affected by certain proposed changes in the by-laws. He added that one of these meetings was an all-day session and that the other lasted for five hours.

The third meeting was held on April 15, 1942. At this meeting a communication was received from Dr. Hugh F. Hare, secretary of the New England Roentgen Ray Society, expressing the desire of that organization that roentgenology and physical therapy be divorced in the sectional setup of the Massachusetts Medical Society and that a new section, to be known as the Section of Roentgenology, be established. The Executive Committee so recommended. The chairman of the Committee on Physical Therapy was acquainted with the recommendation. The Secretary then moved the adoption of this recommendation by the Council. This motion was seconded by Dr. Carl Bearse, Norfolk, and carried by vote of the Council.

The Secretary said that the fourth meeting was held on May 6, 1942. He added that Dr. Edward L. Kickham, Norfolk, was named as the choice of a special committee appointed to select a medical director for Massachusetts Medical Service and that this choice was confirmed by the Executive Committee. The Secretary moved that the Council of the Massachusetts Medical Society approve this act of the Executive Committee. This motion was seconded by Dr. George Leonard Schadt, Hampden, and so ordered by vote of the Council.

The Secretary announced that at the same meeting the Executive Committee, acting in the name of the Massachusetts Medical Society, approved of a board of directors for Massachusetts Medical Service (for personnel of the Board, see Appendix No. 2). He moved that the Council approve this act of the Executive Committee. This motion was seconded by Dr. John B. Hall, Norfolk, and so ordered by vote of the Council.

The Secretary said, for the information of the Council, that, at a meeting of the members of the Massachusetts Medical Service, all members present signed a petition for the incorporation of Massachusetts Medical Service, Mr. E. L. Twomey was elected clerk, Dr. Charles S. Butler, treasurer, and Dr. Edward L. Kickham was named as the members' choice for the medical directorship of the proposed corporation.

The Secretary spoke of an emergency session of the Executive Committee held on May 15, 1942,

at the request of Dr Reginald Fitz, chairman for the Procurement and Assignment Service in Massachusetts. He said that Dr Fitz proposed the following question:

Would the Executive Committee of the Massachusetts Medical Society be willing to recommend to the Council on Medical Education and Hospitals of the American Medical Association during the present emergency, that men from unrecognized schools who have spent four academic years of thirty-two weeks each in a school legally chartered to teach the practice of medicine who have received a diploma as a doctor of medicine from such a school, who are licensed to practice medicine in a sovereign state who have had a year's internship in a registered hospital (not necessarily one approved by the American Medical Association for intern training), and who are American citizens be eligible for commission in the armed forces with the proviso that such men be declared available for this distinction by the local and state committees for procurement and assignment in the area where they reside and on the written recommendation of five doctors in such areas who are graduates of recognized schools.

The Secretary said that the Executive Committee answered the question in the affirmative. The Secretary then moved that the Council approve this act of the Executive Committee. The motion was seconded by Dr Phippen.

Dr Reginald Fitz, Suffolk, in speaking for the adoption of the motion, said that he had recently been in Chicago and that he had placed this matter before the Council on Medical Education and Hospitals of the American Medical Association and likewise before a special committee from the American Association of Medical Colleges. He added that these groups, while friendly toward the proposition and sympathetic with its purposes felt that it was largely a local matter that should be handled by the Massachusetts Medical Society itself.

Dr John J. Curley, Worcester North, in speaking against the adoption of the motion, said that if we give unanimous support to the motion we are recommending that Middlesex men are capable and should be allowed in the armed forces of the United States. He added that we are told that graduates of approved medical schools will not volunteer. He said that he did not believe that this was so. Medical men of Massachusetts, he continued, have been waiting for the Procurement and Assignment Service to tell them when and where they are going to war and this agency has absolutely no power to tell anybody when and where they are going to war.

Dr Phippen said that, as chairman of Procurement and Assignment Service of the First Corps Area, he thought it necessary that he should talk on this subject. He spoke as follows:

I think it is incumbent upon me to say a few words. In the first place, let me say that the Procurement and Assignment Service has had the most hearty and cordial relations with the selective service board with the Surgeon General's Office of the Army and of the Navy, and with the United States Public Health Service. We are not in any argument at all with them. It is perfectly true that the Procurement and Assignment Service cannot tell a man that he should go to war and we cannot tell him he should stay out of it. All we can do is to say that he is available for military service or that he is essential to his community.

The graduates of second rate schools have presented a problem that has been very difficult to handle. The Surgeon General of the Army has already issued an edict that any graduate of a Class B medical school who is registered to practice medicine in his state who is practicing medicine in his state, who is a member of his state medical society and who can be vouched for by five graduates of an approved medical school is eligible for a commission in the Army. That edict has gone through and has been issued. The selective service boards are all cognizant of that fact. These boards do not want to induct a man who has had a medical education or any medical qualification at all into service to carry a musket. That is silly on the face of it. The Army needs doctors.

We hope that this motion will prevail. We feel that graduates of Middlesex and other second rate schools can be taken into the Army and be adequately trained in the Army and can be made efficient doctors. The Army certainly can handle these men a great deal better than we can handle them in civilian practice. And it is not sensible to leave these men behind to do all the practice left behind by graduates of first class medical schools. We sincerely hope that the Surgeon General of the Army will take these men into the service, will put them in training camps and will help to better their medical education—and we believe that he will. There is a pool of six or seven—possibly more—doctors in Massachusetts in this grade, men really needed by the service. Most of these boys want to go. I have had interviews with any number of them. They come to me and say, "Why can't I go?" I should like to go and do my share. But just because I am a graduate of a second rate school they won't let me and I don't see why I can't serve my country just as well as the graduates of a Grade A school. And he is right. He has a right to serve his country if he wants to. But we want to make that man carry a musket. It is silly. I sincerely hope that this motion will prevail. It is a problem we have considered at great length. We get very little satisfaction in talking with people who do not know anything about it. It does prevail in Illinois but not elsewhere. I sincerely hope that this motion will be carried.

Dr Herman C. Peterson, Norfolk, pointed out that, at the moment we are in a fight for our lives and that it does not make any difference whether or not we are going to be dislocated so far as our practice is concerned.

He spoke also of knowing certain graduates of nonapproved schools who were capable and ethical in their practice. He added that these men want

to do their part and they should be given some consideration.

There was a demand for the question from several sources. The motion was put by Dr. Ober, and it was so ordered by vote of the Council.

The Secretary moved the acceptance of the report of the Executive Committee as a whole. This motion was seconded by Dr. Hall and so ordered by vote of the Council.

*Committee on Membership*—Dr. G. Colket Caner, Suffolk, chairman.

This report (Appendix No. 3) was presented by Dr. Caner. It recommended that two fellows be allowed to retire, that five fellows be recommended for affiliate fellowship in the American Medical Association, two fellows be allowed to resign, that the dues of two fellows be remitted, that three fellows be allowed to change their membership from one district to another without change of legal residence and that seven fellows be recommended for readmission.

The report further recommended that the Council rescind its action of February 4, 1942, whereby it deprived Dr. George B. Coon, of Greystone Park, New Jersey, of fellowship for nonpayment of dues. Dr. Caner announced that his committee had learned that Dr. Coon died on January 18, 1941.

Dr. Fitz moved that this report and the recommendations contained therein be adopted. The motion was seconded by Dr. Phippen, and it was so ordered by vote of the Council.

*Committee on Financial Planning and Budget*—Dr. John Homans, Suffolk, chairman.

The Secretary read a letter from Dr. Homans in which he said that his committee had nothing to report.

*Committee of Arrangements*—Dr. William T. O'Halloran, Suffolk, chairman.

Dr. O'Halloran announced that Dr. Conrad Wesselhoeft, Suffolk, would take Dr. Place's spot on the scientific program tomorrow, that the annual dinner would take place in the Georgian Room instead of the Salle Moderne, that Dr. Frederick J. Lynch would act as chairman at the fourth general session on Wednesday afternoon and that the Section of Obstetrics and Gynecology had changed the place of its meeting and luncheon on Wednesday noon.

Dr. O'Halloran moved the adoption of this report as one of progress. The motion was seconded by Dr. Isaac R. Jankelson, Norfolk, and it was so ordered by vote of the Council.

*Committee on Publications*—Dr. Richard M. Smith, Suffolk, chairman.

No report.

*Committee on Ethics and Discipline*—Dr. Ralph R. Stratton, Middlesex East, chairman.

This report (Appendix No. 4) was presented by Dr. William J. Brickley, Suffolk, who said that the committee held two meetings since its last report and that it feels that a careful study of the *Code of Ethics* of the Massachusetts Medical Society and that of the American Medical Association by the fellows would lighten, to a considerable extent, the work now carried on by it.

Dr. Brickley moved the acceptance of the report. This motion was seconded by Dr. Edwin D. Gardner, Bristol South, and it was so ordered by vote of the Council.

*Committee on Medical Education*—Dr. Robert T. Monroe, Norfolk, chairman.

The report (Appendix No. 5) was offered by Dr. Monroe. He said that his committee had held two meetings. At the two meetings, 53 graduates of foreign medical schools were considered, of whom 31 (59 per cent) were accepted, as compared with 92 last year, of whom 64 (69 per cent) were accepted. The prediction that the number of applicants from foreign schools would decrease has proved true so far. Also, 87 graduates of unapproved domestic medical schools were considered, of whom 49 (56 per cent) were accepted. This compares with 80 a year ago, of whom 27 (33 per cent) were accepted. There seems to be no change in the number of applicants from these schools, and in general the local boards of membership found in their favor more often than they have done in the past. During the year only 130 graduates of approved schools applied, or 10 less than the number in the other two categories. Some of this falling off may be attributed to the claims of the armed forces on these men. However, the continued decrease, both in numbers and proportions, of graduates of Class A schools seeking membership in the Society is a source of real concern to the committee and merits serious study. Dr. Monroe added that a list of medical schools approved by the committee was appended to the report.

Dr. Monroe moved that the report be accepted. This motion was seconded by Dr. Phippen, and it was so ordered by vote of the Council.

*Committee on State and National Legislation*—Dr. Henry C. Marble, Suffolk, chairman.

This report (Appendix No. 6) was offered by Dr. Marble, who moved its acceptance. This mo-

ion was seconded by Dr Richard M Smith, Suffolk, and it was so ordered by vote of the Council

*Committee on Public Health*—Dr Francis P Denny, Norfolk, chairman

No report

*Committee on Medical Defense*—Dr Arthur W Allen, Suffolk, chairman

The report\* was read by Dr Allen. It reads as follows:

There are at present seven cases pending. During the past year, two cases have been successfully disposed of—one being dismissed for lack of prosecution and the other having been carried to the Supreme Judicial Court after a trial judge had directed a verdict for the defendant in the proceedings of 1940. The Supreme Judicial Court upheld the action of the trial judge.

One new case has been accepted for defense during the past year.

Since many of our fellows are going into military service, the question has been raised regarding the possibility of lawsuits while on active duty. We have obtained an opinion from our attorneys regarding this point and quote in part as follows:

It would seem to me that it would be desirable for members of the medical profession who are in the United States Army or Navy to proceed on the assumption that there might be liability for negligent treatment. In the first place, the law is not clear. In the second place, whether or not there can be a recovery against a man in these circumstances, he cannot prevent suits being brought against him and, if suit is brought, he is put to the expense of engaging a lawyer to defend him. Furthermore, although he is in the Army and engaged in his army duties most of the time, he may be called upon under some circumstances to treat someone who is a civilian in which case there is no doubt that he is liable for negligence. It should be borne in mind that the fact that a doctor is not paid by his patient for the treatment he renders has no bearing on the question whether or not the doctor can be sued. I would therefore recommend that those members of the medical profession who have in the past carried malpractice insurance should in order to be on the safe side continue to do so while they are in the military service.

The above opinion is in accordance with editorials on the subject in the *Journal of the American Medical Association*, page 936, issue of September 13, 1941, and in the *New England Journal of Medicine*, page 700, issue of April 23, 1942.

It seems to the committee that this recommendation by our attorneys regarding our members and their malpractice insurance should apply also to the members who do not carry malpractice insurance. In members who do not carry malpractice insurance, the fact that they remain members in good standing while in military service without the payment of dues, may cause them to be careless about re-establishing their status in the Society when they are released from military service. It is recommended therefore that all members be careful to make known their return to a

civilian status as soon as they are discharged from military service since it is necessary for them to be members in good standing at the time of an alleged malpractice if they are to benefit from the legal support given by the Society under such circumstances.

Dr Allen moved the acceptance of the report and the adoption of the recommendations contained therein. The motion was seconded by Dr Hall, and it was so ordered by vote of the Council.

*Committee on Permanent Home*—Dr William H Robey, Suffolk, chairman

Dr Robey reported as follows:

At a meeting of the Committee on Permanent Home held on May 13, 1942, it was voted that it is inadvisable at present for the Massachusetts Medical Society to purchase and furnish a building to be used as a headquarters house. Recently we have considered two buildings, one quite near the Boston Medical Library and one quite remote from it but neither would be satisfactory. From time to time I have discussed this problem with members living in and out of Boston, and I have yet to find any member who has expressed the slightest enthusiasm over such a project. It would be difficult to secure at present any space which would be superior to what we have now in the Boston Medical Library. Later, even more space may be available in the library building.

The *New England Journal of Medicine* is satisfactorily located in the library building and the editors find the library a very necessary adjunct. All bibliographical references cited in manuscripts are checked in the library before publication.

Many of us would deplore a separation of the Society from the library and believe that the Massachusetts Medical Society should do all in its power to assist the Boston Medical Library, which, as many of us know, is the fourth in importance in the United States.

Dr Robey moved that the decision of his committee be accepted. This motion was seconded by Dr David Cheever, Suffolk, and it was so ordered by vote of the Council.

Dr Robey moved that the President appoint a committee of five members, one of whom shall be the Treasurer of the Massachusetts Medical Society, to see if anything can be done by the Society to help the Boston Medical Library. This motion was seconded by Dr Albert A Hornor, Suffolk, and it was so ordered by vote of the Council.

#### REPORTS OF SPECIAL COMMITTEES

*Committee on Cancer*—Dr Shields Warren, Suffolk, chairman

No report

*Committee on Public Relations*—Dr Elmer S Bignall, Essex North, secretary

No report

*Committee on Tax-Supported Medical Care*—Dr Bignall, chairman

\*This report is here reproduced in toto because of its great importance to members of the Massachusetts Medical Society.

The report (Appendix No. 7) was offered by Dr. Bagnall, who moved its adoption. The motion was seconded by Dr. Horner, and it was so ordered by vote of the Council.

*Committee Concerned with Prepayment Medical-Care Costs Insurance*—Dr. James C. McCann, Worcester, chairman.

No report.

*Committee Concerned with Postpayment Medical-Care Costs through Banks*—Dr. Bagnall, chairman.

Dr. Bagnall read the report (Appendix No. 8). This report recommended that this plan be adopted in principle, the details to be worked out by the Committee on Public Relations and initiated when completed.

Dr. Bagnall moved the adoption of the recommendation. This motion was seconded by Dr. Gardner.

Dr. Schadt inquired how this scheme compares with the method of financing offered by the Morris Plan. Dr. Bagnall said that the Morris Plan group of banks in this area vary in their interest charges. He added that he had in his book some of the rates of interest charged for carrying these loans and that none were anywhere near as favorable as this one.

Dr. Ober put the motion, and it was carried by vote of the Council.

*Committee on Postgraduate Instruction*—Dr. Reginald Fitz, Suffolk, chairman.

Dr. Fitz, in reading the report (Appendix No. 9), said that interest in postgraduate study had met a great distraction—the war. He added that in 1941-1942 twelve districts did not have any course, while nine continued with greatly reduced enrollment. He complimented the faculty on the excellence of its service.

He said that the Executive Committee and Program Committee of the New England Postgraduate Assembly, at a meeting held on May 12, 1942, had voted to postpone the assembly for the duration. He added that this decision met with the approval of the other New England state medical societies.

He finally announced that the committee is studying the problems of postgraduate instruction in the field of industrial medicine, particularly those related to defense industries, and that an announcement concerning this would appear in the *New England Journal of Medicine* during the summer.

He moved the adoption of the report. This motion was seconded by Dr. Petterson, and it was so ordered by vote of the Council.

*Committee on Physical Therapy*—Dr. Franklin P. Lowry, Middlesex South, chairman.

Dr. Lowry said in this report (Appendix No. 10) that there are four excellent schools for training physical therapy technicians in Greater Boston. He added that there are also several other schools operated largely from a commercial viewpoint. He added that the training which the latter give is superficial. An article pertaining to the selection of schools for the training of physical therapy technicians is to be printed in *Massachusetts Teacher*, a publication that reaches 27,000 teachers. Dr. Lowry stated that he believed that this article would be of special help to those concerned with vocational guidance.

He moved the adoption of the report. This motion was seconded by Dr. Schadt, and it was so ordered by vote of the Council.

*Committee to Consider Expert Testimony*—Dr. George Leonard Schadt, Hampden, chairman.

This report (Appendix No. 11), offered by Dr. Schadt, spoke of the difficulties that the committee had encountered since its creation in 1936, in consequence of which not very much has been accomplished.

Dr. Schadt moved the adoption of the report. This motion was seconded by Dr. Gardner.

Dr. Ober, in this connection, spoke of a talk on this subject that he gave last winter before the Massachusetts Law Society. He added that the officers of that society promised that a committee would be appointed to collaborate with the committee of this Society. He pointed to Minnesota as evidence of how fruitful such collaboration might be.

The motion was adopted by vote of the Council.

*Committee on Industrial Health*—Dr. W. Irving Clark, Worcester, chairman.

No report.

Dr. Ober referred to three March issues of the *Journal of the American Medical Association*, which outline the functions of such a committee. He added that we should work with the Industrial Health Council of the American Medical Association.

*Committee on Army Medical Library and Museum*—Dr. Henry R. Viets, Suffolk, chairman.

No report.

*Committee to Examine WPA Records*—Dr. Guy L. Richardson, Essex North, chairman.

Dr. Richardson spoke in this report (Appendix No. 12) of the reduced number of WPA accidents consequent on the decreased employment under this auspices. He added that the State Compen-

sation Officer felt that this committee had been of immeasurable help in adjusting unreasonable charges and claims

He moved the adoption of the report This motion was seconded by Dr William E Browne, Suffolk, and it was so ordered by vote of the Council

*Committee on Maternal Welfare*—Dr Judson A Smith, Suffolk, chairman

No response

*Committee on Rehabilitation*—Dr William E Browne, Suffolk, chairman

Dr Browne in this report (Appendix No 13) spoke of the several steps that the committee had taken to make the Massachusetts Medical Society of help to the selective service officials in the matter of the rehabilitation of rejected selectees He added that Colonel Donald E Currier, of the Massachusetts Selective Service System, had expressed his willingness to use the machinery of the district medical societies in determining the qualifications of certain doctors suggested by various selective service boards throughout the state and by others

Dr Browne asked the Council to approve the action of the Committee on Rehabilitation in insuring those in charge of selective service boards in Massachusetts that the various district medical societies and the Massachusetts Medical Society as a whole would co-operate in this matter

Dr Browne moved that the action of the Rehabilitation Committee be approved This motion was seconded by Dr William M Collins Middlesex North, and it was so ordered by vote of the Council

*Committee to Study the Practice of Medicine*—Dr Dwight O Harr, Middlesex South, chairman

No report

*Committee of One to Visit Various State Aided Cancer Clinics*—Dr Channing C Simmons Suffolk

No response

*Committee on Procurement and Assignment\**—Dr Reginald Fitz, Suffolk, chairman

Dr Fitz read his report (to be published as an original article in the July 2 issue of the *Journal*) and moved its acceptance The motion was seconded by Dr Charles F Wilinsky, Suffolk

Dr Carl Berse, Norfolk, asked the following question, "Inasmuch as the draft age is forty five, what is the necessity for selecting the figure forty two years?" Dr Fitz, by way of answering this question, stated that the Surgeon General of the

Army has said, over and over again, that what they want are a certain number of men of the rank of a first lieutenant, a smaller number of men of the rank of captain, a fewer number still of the rank of major and practically no lieutenant colonels or colonels It has been found out by past experience that a man who is forty five years old has to be given a rank higher than lieutenant because he will not do the job of lieutenant so well as a younger man Therefore, they are trying to get the younger men first, and then they will go later to this older group if they cannot obtain the necessary number of younger men that they so vitally need

Dr Raymond A McCarty, Middlesex South asked if a man who has been cleared by the Procurement and Assignment Service is notified by this agency provided he has already volunteered Dr Fitz replied that, as Dr Curley brought out earlier, the Procurement and Assignment Service should carry a man until that man volunteers, so that in any district a man must be cleared by Washington before he can volunteer for service

Dr Fitz's motion to adopt the report was carried by vote of the Council Dr Fitz was granted permission to present this report to the third general session of the Society on Wednesday morning, May 27

### *Committee on Nominations*

Dr Guy L Richardson Essex North, reported for the committee the following list of officers

For president elect Roger I Lee Suffolk  
For vice president Peirce H Leavitt Plymouth  
For secretary Michael A Tighe Middlesex North  
For treasurer Charles S Butler Suffolk  
For orator Edward P Bagg Hampden

These nominations were greeted with applause

Dr Ober asked for nominations from the floor There were none Dr Berse moved that the nominations be closed Dr Fitz seconded the motion, and it was so ordered by vote of the Council

Dr Wilinsky moved that the Secretary be instructed to cast one ballot bearing the names submitted by the Committee on Nominations This motion was seconded by Dr Jankelson, and it was so ordered by vote of the Council The Secretary announced that he had complied with this direction

Dr Ober declared amid great applause these men elected

### NEW BUSINESS

President Ober announced his nominations for the various standing and special committees for 1942 and 1943 These nominations were confirmed

\*This is not a committee of the Massachusetts Medical Society as such, but a committee of the Society to study the problem of selective service.

by vote of the Council. (The list will be published with the proceedings of the Society in the July 9 issue of the *Journal*.)

Dr. Ober announced the death of two councilors.

Dr. Charles H. Dalton, of Somerville, died February 12. He was in his sixty-sixth year.

Born in Charlottetown, Prince Edward Island, Dr. Dalton received his degree from McGill University Faculty of Medicine in 1901. He was on the staff of the Somerville Hospital, and was a fellow of the American Medical Association.

He is survived by his widow and five sisters.

On motion of the Secretary the Council stood in silence for one minute in tribute to the memory of Dr. Dalton.

Dr. William J. Delahanty, of Worcester, died May 10. He was in his eighty-fifth year.

A native of Fitchburg, Dr. Delahanty received his degree from Dartmouth Medical School in 1883. He was an incorporator and a member of the staff of St. Vincent's Hospital, and was on the staff of the Worcester City Hospital for more than fifty years. He was a trustee of the Worcester State Hospital, and was a fellow of the American Medical Association.

On motion of the Secretary, the Council stood in silence for one minute in tribute to the memory of Dr. Delahanty.

Dr. Ober read a communication from the Woman's Auxiliary of the American Medical Association asking that a branch of this auxiliary be set up in Massachusetts. The Secretary moved that the communication be referred to the Executive Committee with the idea of having this committee explore the possibilities of setting up a woman's auxiliary in Massachusetts as part of the Woman's Auxiliary of the American Medical Association. This motion was seconded by Dr. Phippen, and it was so ordered by vote of the Council.

The Secretary presented two nominations for honorary fellowship in the Massachusetts Medical Society: Dr. Carl R. Doering — sponsored by Dr. Eliot Hubbard, Jr., Middlesex South, and Dr. Hilbert F. Day, Middlesex South — and Dr. Walter F. Dearborn — sponsored by Dr. Fabyan Packard, Middlesex South, and Dr. Day. Dr. Day moved that these nominations be referred to the Committee on Membership. This motion was seconded by Dr. Richard M. Smith, Suffolk, and it was so ordered by vote of the Council.

Dr. Ober read a communication from the Hampden District Medical Society inviting the Massachusetts Medical Society to hold its next annual meeting in Springfield. Dr. George A. Moore, Plymouth, moved that the invitation be accepted. This motion was seconded by Dr. Charles C. Lund, Suffolk, and it was so ordered by vote of the Council.

The Secretary presented two certificates for membership in the Massachusetts Medical Society irregularly certified by two boards of censors. He explained that the fault in both these cases lay in the nonobservance of Chapter V, Section 2 (a), as this section relates to the timetable governing the admission of graduates of approved medical schools to the Massachusetts Medical Society. The applications were received too late and they were not advertised in the *Journal*. Dr. H. Quimby Gallupe, Middlesex South, said that this matter was discussed in the meeting of the supervising censors held earlier in the day. He added that he was a member of one of the boards of censors certifying one of these candidates and that his board had so acted because it wanted some definite decision in the matter by the Council. This decision would guide his board and all other boards when and if similar circumstances arose. He pointed out that it would be very difficult for doctors entering the service to be promoted if they were not members of their state societies. He said there was a disposition among the supervising censors to facilitate such admissions in the case of graduates of approved schools. With this thought in mind, he offered the following motion:

The supervising censors recommend that Chapter V, Section 2 (a), of the by-laws of the Massachusetts Medical Society, as this section relates to the timetable governing graduates of approved schools in their applications for membership in the Massachusetts Medical Society, be waived, in the interest of those who are either in or who contemplate entering the armed forces of our country and that this regulation shall prevail for the period only of the present emergency.

This motion was seconded by Dr. Petterson.

Dr. Charles E. Mongan, Middlesex South, in seeking information, asked if this motion were passed would the by-laws of the Society be thereby nullified or amended. There was a great deal of debate following Dr. Mongan's question, in which Dr. Petterson, Dr. Frothingham, Dr. Collins, Dr. Mongan, Dr. George C. Tully, Worcester, Dr. W. A. R. Chapin, Hampden, Dr. Cheever, Dr. Fitz, Dr. Denny, Dr. Hornor, Dr. Schadt, Dr. Browne and Dr. Bagnall participated.

Dr. Ober inferentially answered Dr. Mongan's question in the affirmative, by ruling Dr. Gallupe's motion out of order. Some informal discussion continued on the subject. Dr. Ober informed the Council that he would consult counsel and report to the Council the following day, at the recessed meeting, the results of such consultation.

The Secretary moved that the Council postpone action on the two irregular certificates until the

recessed meeting of the Council This motion was seconded by Dr. Mongin, and it was so ordered by vote of the Council.

Dr. Ober called on the Secretary to read a letter that concerned the approving authority for schools for nurses (Appendix No 14). Dr. Mongin moved that this communication be referred to the Committee on Medical Education The motion was seconded by Dr. Horace P. Stevens, Middlesex South, and it was so ordered by vote of the Council

At this point, 10:30 p. m., the annual meeting of the Council recessed until Tuesday, May 26, 1942

\* \* \*

The annual meeting of the Council reconvened at 2-45 p. m., Tuesday, May 26, 1942, in the Salle Moderne, Hotel Statler, Boston. Dr. Ober presiding.

Dr. Ober called on the Committee on Nominations for a nomination for the office of assistant treasurer. Dr. Guy L. Richardson, reporting for this committee, named Dr. Eliot Hubbard, Jr. Dr. Ober called for nominations from the floor. There were none. Dr. Hornor moved that the nominations be closed. This motion was seconded by Dr. Fitz, and it was so ordered by vote of the Council. Dr. Smith moved that the Secretary cast one ballot for assistant treasurer bearing the name of Dr. Eliot Hubbard, Jr. The Secretary announced that this direction had been complied with. Dr. Ober declared Dr. Eliot Hubbard, Jr., assistant treasurer of the Massachusetts Medical Society for the year 1942-1943.

Dr. J. Harper Blaisdell, Middlesex East, moved that the councilors elected in 1942 shall continue to serve in 1943 until after the annual meeting of the Society. This motion was seconded by Dr. Hornor, and it was so ordered by vote of the Council, after the Secretary had explained that under the new by-laws the councilors elected by the districts in 1943 would not take office until after the annual meeting of the Society in 1943.

Dr. Ober submitted his nominations for the newly created Committee on Industrial Health. The list will be published with the proceedings of the Society in the July 9 issue of the *Journal*. The confirmation of these nominations was moved by Dr. Smith. This motion was seconded by Dr. Fitz, and it was so ordered by vote of the Council.

The Secretary again called the Council's attention to the two irregular certifications for membership in the Massachusetts Medical Society, action on which had been postponed earlier in the annual meeting of the Council. He moved, in view

of the action of the annual meeting of the Society, that these men be declared members of the Massachusetts Medical Society. This motion was seconded by Dr. Walter H. Pulsifer, Plymouth, and it was so ordered by vote of the Council.

Dr. Ober announced that the business on the docket had been completed. Dr. Blaisdell moved adjournment. The motion was seconded by Dr. Pulsifer, and on a vote, the Council adjourned at 2:55 p. m.

MICHAEL A. TIGHE, *Secretary*

## REPORT OF THE EXECUTIVE COMMITTEE

The Executive Committee has had five meetings since the stated meeting of the Council in February.

The February 25 and March 4 meetings represented hearings which were given to the Committee on By-Laws; present likewise at these hearings were the committees likely to be affected by proposed changes in the by-laws. One of these meetings was an all-day session and the other lasted for five hours.

The third meeting was held on April 15, 1942. The committee was in receipt of a communication from Dr. Hugh F. Hare, secretary of the New England Roentgen Ray Society, expressing the desire of that organization that radiology be divorced from the Section of Radiology and Physiotherapy and that a separate Section of Roentgenology be set up. The committee so recommended. The chairman of the Committee on Physical Therapy was informed of this action.

The meeting of May 6 was concerned with the organization of Massachusetts Medical Service.

At the stated meeting of the Council, February 4, 1942, the following recommendation of the Committee on Prepayment Medical-Care Costs Insurance was adopted: "That a special committee be appointed by the Executive Committee to select an executive director." (The reference is to a medical director of Massachusetts Medical Service.)

Dr. Peirce H. Leavitt, chairman of the committee appointed by Dr. Ober under this direction, reported that Dr. Edward L. Kickham, of Norfolk, was the unanimous choice of this committee for the position. Dr. Kickham is a resident of Brookline where he was born November 6, 1895. He enlisted in the armed forces of our country in May, 1917, as a private—interrupting his college course to do so. He was honorably discharged December, 1918, a lieutenant in the infantry. He was graduated from Boston College in 1919 and Tufts College Medical School in 1923. He interned at the Carney and New York Lying-In hospitals. He has practiced his profession in Boston since. He is a fellow of the American College of Surgeons and a diplomate of the American Board of Obstetrics and Gynecology. He is a member of the staffs of St. Elizabeth's and Carney hospitals. He is an instructor in gynecology at Tufts College Medical School and assistant surgeon at the New England Medical Center. He is a member of the Massachusetts Medical Society and has been a councilor to the body from the Norfolk District for several years. He holds membership in the American Medical Association and the New England Gynecological and Obstetrical and the Boston Obstetrical societies.

The choice of Dr. Kickham for this position was approved by the Executive Committee.

## REPORT OF THE COMMITTEE ON STATE AND NATIONAL LEGISLATION

Since the last report of this committee in the fall of 1941, there has been no session of the Massachusetts Legislature that has considered any bills of concern to this society. In the Capitol, the present emphasis is on the conduct of the war. There are many bills pending that so far have remained dormant. These bills concern health insurance, hospitalization, social security and medical care. There are also bills relative to the administration of public health. All these bills are being followed by the several interested bodies in Washington. After the present crisis, surely many of these bills will be revised and require much study and consideration.

7. That the Council rescind its action of February 4, 1942, whereby it deprived of fellowship for nonpayment of dues George B. Coon, of Greystone Park, New Jersey. (The committee has recently learned that Dr. Coon died on January 18, 1941. Previous to that time he had been an esteemed fellow of the Society for many years.)

G. COLKET CANER, *Chairman*

#### APPENDIX NO. 4

##### REPORT OF THE COMMITTEE ON ETHICS AND DISCIPLINE

The major portion of the year's work of the Committee on Ethics and Discipline was reported on February 4, 1942, to the Council and will be found under Appendix No. 8 (page 434) in the March 12, 1942, issue of the *New England Journal of Medicine*.

Subsequent to that meeting the committee has held two full-day meetings, discussing and settling cases which fell into the different classes noted in our previous report.

The committee feels that a careful study of the *Code of Ethics* of the Massachusetts Medical Society and that of the American Medical Association by the fellows would lighten, to a considerable extent, the work now carried on by it.

FRED R. JOUETT

ARCHIBALD R. GARDNER

RALPH R. STRATTON, *Chairman*

#### APPENDIX NO. 5

##### REPORT OF THE COMMITTEE ON MEDICAL EDUCATION

Two regular meetings were held before the November and May censors' examination of candidates for admission to the Society, and the qualifications of the candidates from foreign medical schools and from unapproved domestic schools were studied. In the very great majority of cases the decisions were in agreement with those of the local boards of membership. Most of the disagreements were settled to the satisfaction of each committee. It is the committee's belief that the local boards are doing their work well, upholding the interest of the Society, as well as those of the candidates. It is also our feeling that most of the boards welcome a review of their decisions by a committee of the Society. Under the new by-laws, this work will henceforth be in charge of the Committee on Membership.

At the two meetings, 53 graduates of foreign medical schools were considered, of whom 31 (59 per cent) were accepted, as compared with 92 last year of whom 64 (69 per cent) were accepted. The prediction that the number of applicants from foreign schools would decrease has proved true so far. Also, 87 graduates of unapproved domestic medical schools were considered, of whom 49 (56 per cent) were accepted. This compares with 80 a year ago, of whom 27 (33 per cent) were accepted. There seems to be no change in the number of applicants from

these schools, and in general, the local boards of membership found in their favor more often than they have done in the past. During the year only 130 graduates of approved schools applied, or 10 less than the number in the other two categories. Some of this falling off may be attributed to the claims of the armed forces on these men. However, the continued decrease, both in numbers and proportions, of graduates of Class A schools seeking membership in the Society is a source of real concern to the committee and merits serious study.

There is appended a list of medical schools approved by the committee.

ROBERT T. MONROE, *Chairman*

University of Kansas School of Medicine, Lawrence, Kansas City.

###### KENTUCKY

University of Louisville School of Medicine, Louisville.

nesses of the districts and the military educational needs as they may affect the medical profession.

On May 12, 1942, the Executive Committee and Program Committee of the New England Postgraduate Assembly voted to postpone the assembly for the duration. This vote was almost unanimous among the New England state medical societies.

The committee announces that the Clinical Congress of the Connecticut State Medical Society will be held next September, further announcement of this event will be made in the *New England Journal of Medicine*.

At the present time the committee is studying the problems of postgraduate instruction in the field of industrial medicine, particularly as it relates to the defense industries. Announcement concerning this phase of postgraduate instruction will be made in the *New England Journal of Medicine* later in the summer.

REGINALD FITZ, *Chairman*  
LEROY E. PARKINS, *Secretary*

## APPENDIX NO 10

### REPORT OF THE COMMITTEE ON PHYSICAL THERAPY

It should be of interest to the members of the Council to realize that in Greater Boston we have four excellent schools for training physical therapy technicians which fulfill every requirement of the American Medical Association. We also have, however, several other schools operated largely from a commercial viewpoint, these provide the pupil with a training so superficial as to be utterly inadequate for a successful career. Cases have come to our attention where the high school teacher who is designated as 'vocational adviser' has probably entirely from ignorance of the situation suggested one of these schools to the inquiring high school senior because of its shorter course. These commercial schools have few or no clinical opportunities and are extremely limited in the quality of their instruction. Their courses are so short that they average but eight months or from three to five half-days each week, this is not one quarter the time required to grasp adequately the basic fundamentals necessary for the work of a physical therapy technician.

Many teachers acting as vocational advisers are too busy to investigate the various schools in the many types of work open to the graduating pupils. Consequently the easiest procedure is to hand out an advertising pamphlet that has been sent from these schools and with it comes to the pupil the implied recommendation of the adviser.

In an attempt to correct this situation your committee has been of practical help by disseminating information concerning the teaching of physical therapy to the Hospital Council of Boston, to occasional private inquirers, to the high school teachers and vocational advisers, and to the State Office of Secondary Education. An article pertaining to the selection of schools for the training of physical therapy technicians is to be printed in *Massachusetts Teacher*, a publication that reaches 27,000 teachers. A small but increasing number of requests are being received by your committee for advice and information pertaining to this phase of our work. This recent undertaking has already accomplished encouraging results.

There are probably a goodly number of counselors who are vitally interested in the schools of their cities. The committee urges that, in justice to our high-school graduates you lend your influence to this problem. This may be done by conferring with the adviser in your high school or by seeing that she gets in touch with the office

of the Massachusetts Medical Society or with this committee, for desired information concerning curriculum, clinical facilities and instruction of these various schools for training physical therapy technicians.

FRANKLIN P. LORRA, *Chairman*  
GEORGE R. MINOT  
ROBERT B. OSGOOD

## APPENDIX NO 11

### REPORT OF THE COMMITTEE TO CONSIDER EXPERT TESTIMONY

Your committee was appointed at the Springfield meeting of the Society in 1936 to consider certain matters included in the report of the Committee on Ethics and Discipline. Since the work of your committee is still incomplete, this must be a report of progress only.

Many difficulties in the work of the committee have been encountered. Many conferences have, however, been held between the chairman and other members. A long illness of the chairman in 1939 further delayed the work, but since the middle of 1940 much groundwork has been laid and considerable accomplished.

It was early appreciated by your committee that to function and accomplish the purpose of its being it would be desirable and necessary to have the help of the Massachusetts Bar Association as well as that of members of the General Court especially those members connected with legal affairs.

The president of the Massachusetts Bar Association from 1940 to 1941 was most co-operative. Unfortunately he left this office before he was able to appoint a committee from the Massachusetts Bar Association to work with our committee. The president of the Bar Association at the present time also is much interested and in December 1941 appointed the late Harold P. Small of Springfield, to serve as chairman of a committee and to select the other members of the committee. Unfortunately, Mr. Small died very suddenly on January 1, and in their delay has ensued.

Mr. Tschol Peterson, a member of the State Senate, has also been most helpful and will continue to be. Mr. Peterson in his many conferences with the chairman stressed the fact that the work of your committee is of necessity of considerable delicacy, that it should be carried out slowly and with the assistance of a committee from the Massachusetts Bar Association is mentioned earlier.

As matters stand at present your committee has been forced to hold in abeyance any further deliberations, subject to the appointment of a committee from the Massachusetts Bar Association or from some other legal society in the State.

GEORGE LEONARD SCHULT, *Chairman*  
DAVID CIEFFER  
JAMES J. GOODWIN

### REPORT OF COMMITTEE TO EQUALIZE DISTRIBUTION AMONG PHYSICIANS OF MEDICAL SERVICE TO WPA EMPLOYEES

As was expected the WPA roll has continued to decrease in numbers. Last month there were approximately 30,000 workmen and the lowest accident case record—

## CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTE-MORTEM AND POST-MORTEM RECORDS AS USED  
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

### CASE 28261

#### PRESENTATION OF CASE

A forty-nine-year-old millworker was admitted to the hospital because of a disturbance of vision and occipital headaches.

For several years before entry, the patient had occasional difficulty in understanding things said to him. He attributed this to "poor hearing." Two years before entry, he began to have suboccipital and less often frontal or parietal headaches once or twice a week and, as a rule, lasting half a day. About a year before entry, the patient became aware of inability to see objects to the left of him. There was no disturbance of central vision. For about three months before entry, the headaches were accompanied by unsteadiness of gait; during the headaches, the patient staggered and tended to fall to the left. He became somewhat irritable, and seemed to be preoccupied with past events. Memory for recent events was impaired. He had to "stop and figure out" his previously habitual duties as a loom-tender in a mill. About this time, he began to regurgitate food and sour material immediately after swallowing. Once he vomited.

The family and past histories were irrelevant.

On admission, the patient appeared well developed and nourished, co-operative, fairly intelligent and well oriented. The heart, lungs and abdomen seemed normal. There was moderate scoliosis of the thoracic spine, with convexity to the right. There was partial left homonymous hemianopsia, the maculae being unaffected. The optic fundi were normal. The right pupil was slightly irregular and slightly smaller than the left; both reacted well to light and distance. Ocular movements were normal. There was no nystagmus. Tests of hearing showed questionable reduction in air conduction in the left ear. The gait was normal, with eyes open or closed. There were slight weakness and slightly increased muscular tone in the left arm. The reflexes were thought to be normal.

The temperature, pulse and respirations were normal. The blood pressure was not recorded.

Examinations of the blood and urine were negative. The blood Hinton reaction was negative. A lumbar puncture gave clear, colorless fluid under

an initial pressure of 280 mm. of mercury. There were 3 lymphocytes per cu. mm.; the total protein was 216 mg. per 100 cc., the gold-sol curve was 0011221000, and the Wassermann reaction was negative.

An electroencephalogram was suggestive of a lesion on the right side near the midline in the parietal region. Roentgenograms of the upper gastrointestinal tract and of the chest were negative.

A ventriculogram showed incomplete filling of the right lateral ventricle, with displacement of both ventricles toward the left. A Mixter punch introduced into the right temporal lobe to a depth of 5 cm. gave the operator a gritty sensation, but examination of the biopsy specimen was negative.

On the nineteenth hospital day, an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR. WILDER PENFIELD\*: Was the patient right handed, or left handed?

DR. CHARLES S. KUBIK: He was right handed.

DR. PENFIELD: Is it permissible to see the x-ray films of the skull?

DR. TRACY B. MALLORY: You are welcome to see them at any moment you like.

DR. PENFIELD: Is there a calcification corresponding to the gritty sensations reported?

DR. AUBREY O. HAMPTON: Here are some plain films taken before the encephalogram. The only calcium I see appears to be in the pineal gland, and if this is the pineal gland it is displaced toward the right and the ventricles toward the left. That is very unusual.

DR. PENFIELD: If one takes the history and physical examination, the patient had a left homonymous hemianopsia, and it is said that there the maculae were not involved. So far as our clinical experience goes, that means that the interruption of the visual fields occurred posterior to the temporal region. On the other hand, one would like to know how carefully the maculae were investigated. The man had evidence of increased intracranial pressure, and one assumes that he had a cerebral tumor. The encephalogram showed displacement from the right to the left, but it seems to me that this calcification is too low and too far anterior to be a pineal body, and one sees in the anteroposterior view calcification at this point that might correspond with that on the right side.

For a snap diagnosis, I should be driven to the conclusion that this man had an expanding lesion, that the calcification probably lay in the expanding

\*Director, Montreal Neurological Institute, McGill University Faculty of Medicine; professor of neurosurgery, McGill University Faculty of Medicine, Montreal.

lesion, and that the expanding lesion was in the right posterior temporal region.

A PHYSICIAN: Temporal?

DR. PENFIELD: Temporal, because of the x-ray findings, which I am accepting. I assume that Dr. Hampton takes that as the proper position for the pineal gland, and that the calcification in the anteroposterior view is on the right side.

DR. HAMPTON: It is on the wrong side for the ventricular displacement.

DR. PENFIELD: Then, may we not assume that this lies in the expanding lesion itself and corresponds with the gritty material that the operator encountered—indicating calcification in the x-ray film in the posterior temporal region?

DR. HAMPTON: It is very small. I do not know. It would be very fortunate if they tapped it.

DR. PENFIELD: At all events, clinically the patient had a lesion that should have been very near the calcified object, and this localization probably gave him homonymous hemianopsia. We have run into a group, about half a dozen, of small calcified neoplasms that occurred in the temporal region, usually deep in the temporal lobe—I am not sure that one or two did not lie on the other side of the inferior horn—and were of a type of neoplasm that is hard to define histologically. We called them—one or two of them, at any rate—hemangioblastomas or hemangiomas of some type. They were not gliomas. They did have vessels in them. We treated one or two by x-ray for long periods. I am thinking of a patient treated by Dr. Charles A. Elsberg. The x-ray picture was similar to that in the case under discussion, although there was a little more calcification. We operated, and there was an area of atrophy and evidence of both atrophy and some expansion.

Do you want me to "stick my neck out"?

DR. MALLORY: That is the custom.

DR. PENFIELD: Then, in spite of the report of the hemianopsia, with the unaffected maculae, which would make it occipital, I assume that this man had a neoplasm in the posterior temporal area, and that it might have been one of those tumors that are made up of many blood vessels that I do not know how to classify histologically.

DR. MALLORY: Would anyone like to ask Dr. Penfield any questions or suggest any alternative diagnoses?

A PHYSICIAN: What is your objection to meningioma?

DR. PENFIELD: A meningioma arising from the lesser wing of the sphenoid would have to be considered, but in our clinic meningioma is very rarely calcified, and if my assumption that this is neoplasm is correct, I should not consider a meningioma.

A PHYSICIAN: Would the total protein in the spinal fluid give you any inkling of the type of tumor?

DR. PENFIELD: I suppose that it suggests proximity of the tumor to the ventricle. I do not believe it indicates the nature of the tumor as a rule, although it might be that this was a neoplasm attached to the choroid plexus, with calcification in it.

A PHYSICIAN: There was considerable ataxia. How do you explain that?

DR. PENFIELD: I should explain it on the basis that the tumor might well have extended into the basal ganglion in some way. The patient had a pyramidal lesion involving the left side slightly. He had no true ataxia in the upper extremities with the eyes opened or closed.

DR. SAMUEL LEWIS: I have no additional information beyond what is available in the abstract.

In retrospect, it is my impression that the gritty sensation was not encountered when the needle was directed toward the temporal lobe. As I remember it, the gritty sensation was encountered when the right needle was directed in the usual position toward the posterior horn of the ventricle; no air was introduced into the right needle, but only into the left ventricle. The picture was satisfactory at that point, and there was no need for further study. There was no question that the gritty sensation was present, even though the biopsy at the time of the ventriculogram was negative, as was later brought out at the operation, when the same material was encountered. The position was not specifically temporal but perhaps seemed to be nearer the midline, and higher—parieto-occipital—according to the actual localization of the findings at operation.

DR. MALLORY: Will you continue and describe your findings at the craniotomy?

DR. LEWIS: I shall read the operative note:

Under intratracheal ether anesthesia, a medium sized temporo-occipital skin flap was turned down to within 2 cm of the midline, with a correspondingly large bone flap under the same area. The dura was incised with the pedicle at the top, toward the front. The cortex appeared normal, but felt soft over the posterior area of the exposure. Probing was done here, and the tumor encountered at a depth of about 4 cm. At this point of the procedure, Dr. John S. Hodgson entered the operation and opened the cortex down to the tumor and took a biopsy. There was no bleeding. (It was accepted at this time that the tumor was a meningioma.) The dura was closed along the anterior margin, the posterior margin of the cortex being left uncovered. Then, while the posterior margin of the scalp flap was retracted, the bone was undercut as far as possible, both from that point and from the bone flap where it was to be apposed—an extensive bone defect being left immediately over the tumor. The dura also had a defect here.

The undercut bone area was drained, as was the incision in the temporal muscle, and the wound was closed in two layers with silk. The patient was given two transfusions. Our plan in doing the operation in this way was to allow the ventricular system to displace the tumor nearer to the cortex at the point where cerebral hernia is certain to occur. At a second stage in six to eight weeks, we shall re-elevate this area of scalp and expect to effect an easier removal of the tumor.

The intention was to allow the tumor to migrate more toward the surface for a second-stage removal.

#### CLINICAL DIAGNOSIS

Parieto-occipital meningioma.

#### DR. PENFIELD'S DIAGNOSIS

Brain tumor (?), hemangioblastoma, posterior temporal region.

#### ANATOMICAL DIAGNOSES

Tuberculous meningitis.

Tuberculoma, posterior parietal region.

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: The first attempt at a punch biopsy provided nothing from which a diagnosis could be made, but at the time of the craniotomy a second biopsy showed the characteristic wall of a tuberculoma, I think considerably to everybody's surprise. The patient then did very well for a long period, and it was three years before he began to develop serious symptoms of a different nature. He came in on the last occasion with a frank meningitis, and died in a comparatively brief period so that we have the findings of the autopsy, which will give us a little better check on the location of the lesion.

Dr. Kubik, will you tell us what the autopsy showed?

DR. KUBIK: There was a tuberculous meningitis. In the right posterior parietal and occipital region, above and lateral to the posterior horn of the ventricle, was a tuberculoma, from 2 to 3 cm. in diameter. This consisted of caseous material surrounded by a dense, fibrous capsule. Near it was a similar, smaller tuberculoma.

DR. MALLORY: Are there any other questions?

DR. PAUL BUCY: I should like to ask Dr. Lewis whether or not, when they found that this was a tuberculoma and in this location, an amputation of the occipital lobe might not have been considered.

DR. LEWIS: A second operation was considered, but the more conservative point of view prevailed. The patient made a surprisingly uneventful recovery. He was watched from the point of view of curiosity rather than from that of doing more about it.

DR. KUBIK: In another patient, operated on in 1931, there was a mass, the size of a small hen's

egg, in the parietal region. This differed from case under discussion in that the lesion was not and contained numerous small caseous foci. patient is still alive, eleven years later.

A PHYSICIAN: Was there any tuberculous elsewhere in the body?

DR. MALLORY: At autopsy, no active tubercles were found outside the central nervous system. Even the lungs were entirely normal.

A PHYSICIAN: How do you explain the nature of the lesion?

DR. MALLORY: I have little doubt that there was originally a pulmonary tuberculous infection, think, if the lungs had been examined with a more technic for Ghon's tubercle, we should have found it.

A PHYSICIAN: Were no tubercle bacilli found?

DR. MALLORY: Yes; they were found in spinal fluid on the last admission.

#### CASE 28262

#### PRESENTATION OF CASE\*

An eight-year-old boy was admitted to the hospital because of sudden progressive "fatness."

The patient was essentially well until three weeks before entry, when he was said to have "fallen into a river" and to have wet his legs. Two weeks before admission, he claimed to have had a "hard head cold," and at approximately the same time his family noted that he was "getting fat." The exact sequence of events was not entirely clear. The "fatness" was steadily progressive in severity, and during the week prior to entry his appetite became poor and he vomited three times but presented no other signs or symptoms of disease, either constitutional or referable to any of his symptoms. On the day before entry, his family physician examined the urine and advised admission to the hospital.

The patient had had the usual childhood diseases, and in addition had had a mastoiditis and a right mastoidectomy and a depressed skull fracture without unconsciousness, six months before entry. He had not had diphtheria or scarlet fever.

The family history was irrelevant.

Physical examination on admission revealed a pale, markedly edematous boy in no acute distress. The skin was dry, with keratinizing plugs in many of the hair follicles and desquamating scaly regions over the back. A small depressed area could be palpated in the left parietal bone. The eyes, including the fundi, were normal. A right mastoidectomy scar and some thickening and retraction of the left eardrum were noted. There was puffing

\*This case is presented through the courtesy of the Children's Hospital, Boston.

the face and eyelids, and the breath was urinous. Minimal dullness and diminution of breath sounds were noted at both lung bases. Otherwise, the lung fields were clear. The heart was described as possibly enlarged slightly to the left. An apical systolic murmur was present, which one observer described as soft and blowing, and another as loud and rough, accompanied by a thrill and transmitted to the base and left axilla. The second observer also described a split mitral second sound. The abdomen was slightly distended, but there were no palpable masses or organs, and no shifting dullness or fluid wave could be made out. The genitalia, extremities and sacral regions were edematous.

The temperature was 98°F., the pulse 88, and the respirations 20. The blood pressure was 135 systolic, 110 diastolic.

Examination of the blood showed a red-cell count of 2,500,000 with 65 per cent hemoglobin, and a white-cell count of 6800 with a normal differential. The urine was cloudy yellow and acid, with a specific gravity of 1.010 and a trace of albumin. It contained 0 to 5 red cells, 0 to 15 white cells, and 1 to 20 granular casts per high-power field. A blood Hinton reaction was negative, as was a tuberculin reaction in a dilution of 1:1000. The serum protein was 3.7 gm. and the nonprotein nitrogen 101 mg. per 100 cc. A throat culture grew out a few colonies of beta hemolytic streptococci and a moderate number of colonies each of pneumococci, *Haemophilus influenzae* and yellow staphylococci.

A roentgenogram of the chest showed enlargement of the heart both to the right and to the left, the total cardiac diameter being 12.1 cm., compared to a total internal diameter of the chest of 20.1 cm. There were also moderate pulmonary congestion and small bilateral pleural effusions. Films of the paranasal sinuses showed moderate irregular thickening of the mucous membranes lining the ethmoid and maxillar sinuses.

The patient was treated with magnesium sulfate orally and parenterally, transfused, and placed on limited fluids and a low-salt, high-protein diet. This resulted in improvement of the edema, but the blood pressure remained about 140 systolic, 100 diastolic. The urine continued to show red cells, white cells, abundant granular and cellular casts, and a trace to a large trace of albumin. A urea-clearance test on the third hospital day showed 6 per cent of normal function. On the sixth hospital day, the nonprotein nitrogen was 133 mg. per 100 cc. On the eighth day, the patient complained of severe sore throat and some cough. He was nauseated and somewhat orthopneic. The temperature was 100°F., and the pulse rapid and weak,

with a pulse deficit. The blood pressure rose to 170 systolic, 120 diastolic. The heart action was rapid, with poor sounds and a gallop rhythm. There was enlargement of the liver, and rales were present over both lung bases. An electrocardiogram showed slight left-axis deviation and suppression of T<sub>2</sub>. The patient was treated with morphine, and rapid digitalization was attempted; however, the pulmonary edema increased in severity, and the pulse became irregular and thready. An electrocardiogram showed a slight prolongation of the PR interval. Terminally, Cheyne-Stokes respirations developed. The patient died on the ninth hospital day, approximately three weeks after the onset of his illness.

#### DIFFERENTIAL DIAGNOSIS

DR. ALLAN M. BUTLER: I should like to remark on a few points in the description of this case. "The skin was dry, with keratinizing plugs in many of the hair follicles and desquamating scaly regions over the back." Such findings are present with a vitamin A or C deficiency but hardly ever in an essentially healthy boy of eight years of age. One can have scaly desquamation, perhaps, following scarlet fever.

"The abdomen was slightly distended, but there were no palpable masses or organs, and no shifting dullness or fluid wave could be made out." One wonders whether the edema masked a slightly enlarged liver. On the other hand one could have these signs of cardiac failure in a patient with acute nephritis without much in the way of enlargement of the liver, since the failure is usually left sided.

"A roentgenogram of the chest showed enlargement of the heart both to the right and to the left." Such cardiac enlargement is common in acute hemorrhagic nephritis.

"There were also moderate pulmonary congestion and small bilateral pleural effusions"—I suppose because of congestive failure.

"An electrocardiogram showed slight left-axis deviation and suppression of T<sub>2</sub>." In other words, there was some myocardial involvement.

Much of this history is typical of the history of an acute initial hemorrhagic nephritis. The patient had an upper respiratory infection two weeks preceding the onset of the present illness. The gain in weight, of course, was due to edema. He had anorexia and vomiting, and the urine contained albumin, red cells and casts. He had hypertension and the signs of myocardial failure. On the other hand, certain facts and lack of information in the history make one wonder whether the autopsy will reveal either some evidence of an antecedent cardiac lesion, a previous nephritis,

which was latent before the present exacerbation, a congenital anomaly, which resulted in diminished renal function, or a previous pyelonephritis, which likewise caused diminished renal reserve. The lack of information pertains to the statement that the patient was essentially well. One wonders whether he was fairly well or really a robust, healthy boy of eight. Then we find that he entered the hospital two weeks after an upper respiratory infection, with pallor and marked edema. Usually, a patient with acute initial hemorrhagic nephritis does not have marked pallor and is not markedly edematous. On the other hand, it is possible to have an acute hemorrhagic nephritis that is accompanied by marked degenerative changes throughout the entire parenchyma of the kidney. Edema then appears very rapidly, and may become as extensive as that seen in nephrosis. Moreover, the patient had a uriniferous breath, which is very rare in acute initial hemorrhagic nephritis.

I should pass over the question of the murmur in the heart as being no evidence of endocarditis or congenital heart disease and say that it was a systolic murmur due to dilatation of the heart such as is observed so frequently in acute hemorrhagic nephritis. The red-cell count of 2,500,000 and the hemoglobin of 65 per cent confirm the pallor and are rather unusual in acute initial hemorrhagic nephritis unless accompanied by very extensive degenerative changes throughout the tubules and general parenchyma of the kidneys—in other words, a very severe fulminating type of hemorrhagic nephritis, which is unusual in children. Next, we notice a specific gravity of 1.010, which in a boy with acute initial hemorrhagic nephritis in the stage of edema is very rare because such patients almost always have oliguria, and the urine concentration is almost always quite good. Oliguria and good specific gravity of the urine are characteristic of initial hemorrhagic nephritis, and this boy seems to have had neither.

In considering the urine sediment, I should like to know whether it was centrifuged, because I know that at the Children's Hospital half the people examine uncentrifuged and half centrifuged sediments and the records rarely show which was done—0 to 5 red cells if uncentrifuged are a lot; if centrifuged, they are not. There were 1 to 15 white cells. White cells predominate over the red cells; this suggests what Addis and Oliver\* call a "degenerative element." Granular casts and epithelial cells are not mentioned.

DR. TRACY B. MALLORY: The report on one centrifuged specimen says that there were 15 to 30 red blood cells and 3 to 5 white blood cells per

high-power field; it was also reported to "loaded" with granular casts and some white blood cell casts, but there is no mention of epithelial cells.

DR. BUTLER: Usually, with a marked element of degenerative changes, there are epithelial cells in the urinary sediment. No mention is made of a urine culture, and sometimes one is surprised to find that there is infection along with what appears to be uncomplicated acute hemorrhagic nephritis.

The serum protein was 3.7 gm. per 100 cc. In the ordinary case of acute initial hemorrhagic nephritis, the serum protein may come down, but usually not to 3.7 gm. in two weeks. If it does, there is usually a marked involvement of the entire kidney. We have such a boy on the ward at the present time, with a serum protein around 3 gm. whose hemorrhagic nephritis from the history appears of apparently short duration, and he puzzled me for that reason.

The nonprotein nitrogen was 101 mg. per 100 cc. That is very high for a patient with initial acute hemorrhagic nephritis and a urine with a specific gravity of 1.010. Usually, such a specific gravity and urine volume suggest that the oliguric stage has been passed, and the nonprotein nitrogen would be on the way down and not high as 100 mg. Certainly, it is too high for a patient with nephrosis.

On the third hospital day,—that is, a week more after the onset of the anorexia and nausea and the finding of abnormal urine sediment by the family physician,—the urea clearance was 10 per cent, and that again is very unusual in a patient with simple initial hemorrhagic nephritis and again indicates to me that there was either some abnormality in the kidney existing at the onset of this acute hemorrhagic nephritis or very extensive nephritis extending far beyond the glomerular involvement of an ordinary hemorrhagic nephritis. On the sixth day, the nonprotein nitrogen was 133 mg.—still going up.

In summary, I should think that this patient had an acute hemorrhagic nephritis, the cause of death being myocardial failure. Autopsy will show a dilated heart; I do not know whether it will be very hypertrophied or not. Usually, in patients who die of myocardial failure during an acute hemorrhagic nephritis, the pathologists find relatively little at examination. This suggests that the myocardial failure is due to a vascular disturbance within the myocardium, similar to that affecting most of the other organs of the body in acute hemorrhagic nephritis. I do not know whether we shall find that this was one of the very diffuse, rapidly progressing types of acute

\*Addis, T., and Oliver, J. *The Renal Lesion in Bright's Disease*. 628 pp. New York: Paul B. Hoeber, Inc., 1931.

initial glomerular nephritis with degenerative changes involving all the parenchyma of the kidney as well as the glomeruli, or whether we shall find that there existed a congenital anomaly, an old renal infection with scarring, or an unnoticed nephritis previous to this acute hemorrhagic nephritis. I believe that the kidneys were large and edematous. With the anemia and with low serum protein, I think that they perhaps were not so red as the usual red swollen kidneys of glomerulonephritis.

#### CLINICAL DIAGNOSES

Acute hemorrhagic nephritis  
Terminal heart failure

#### DR. BUTLER'S DIAGNOSES

Hemorrhagic nephritis  
Cardiac dilatation  
Hypertension  
Myocardial failure, with congestion characteristic of right-sided and left-sided cardiac failure  
Either pre-existing congenital anomaly or infection of urinary tract, pre-existing nephritis or superimposed degenerative changes involving all elements of renal parenchyma

#### ANATOMICAL DIAGNOSES

Acute and chronic glomerulonephritis, with degenerative vascular lesions in kidneys, terminal  
Anasarca  
Cardiac hypertrophy, with terminal congestive failure  
Congenital incomplete defect of interventricular septum  
Tracheobronchitis and bronchopneumonia

#### PATHOLOGICAL DISCUSSION

DR. SIDNEY FARBER\* The clinical diagnoses were acute hemorrhagic nephritis and terminal cardiac failure. At post mortem examination, we found massive edema of the periphery, fairly well marked ascites, marked pleural effusion

and pericardial effusion. There was terminal congestive failure, with pulmonary edema and marked congestion of the liver and the abdominal viscera. The kidneys were somewhat enlarged, — about 25 per cent above weight, — red and rather congested. Some of the redness disappeared after standing. The parenchyma was more yellow than appeared at first glance. There was a diffuse glomerulonephritis perfectly consistent with what one would expect from the history. There were two other findings, glomerular lesions that must have gone back at least a year and were diffuse and not too numerous, but were easily found throughout both kidneys, and the blood vessels showed fibrin degeneration of the walls, particularly in the afferent arterioles, and in the glomerular loops.

The heart was almost twice the normal weight, and there was, as Dr. Butler indicated, very little evidence of cardiac inflammation. There was some fatty degeneration of the myocardium as is sometimes found in cases of this kind, and a good deal of edema of the myocardium. I neglected to mention that, in addition to the pulmonary edema and congestion, there was a very important tracheobronchitis, with destructive lesions in the bronchioles.

The brain was considerably increased in weight, with a definite pressure cone at the base. The heart showed, in addition to the findings already described, a congenital malformation. It is the first of its kind that I have had the opportunity to see. Here, at the base of the aortic valve in the region of the undefended space where the interventricular septal defect is so often found, was an incomplete defect of the septum with no actual communication between the left and right sides of the heart. We have an adequate basis for a murmur, then, if one was actually heard.

In summary, this was a case of acute glomerulonephritis, with evidence of older glomerulonephritis that must have gone back at least a year. In the kidneys, there was also evidence of acute degenerative lesions in the arterioles and glomerular capillaries, which, for want of a better explanation, I should associate with the hypertension. The other findings were secondary to the kidney disease.

## MATERNAL MORTALITY

TEN years ago, the appallingly high maternal mortality in the United States was a national disgrace, and there were insistent demands from both the laity and the medical profession that something be done about it. Now it begins to look as if something had been accomplished. In 1939, the United States had a maternal mortality of 4.0 per 1000 live births—the lowest recorded in this country; in 1930, the rate was 6.7. In 1933, the rate in Massachusetts was 6.7, and it has dropped every year but one since then, to a level of 2.8 in 1940.

Many factors have combined to produce this lowering of maternal mortality. Doubtless, one of the most important has been the extension and

improvement of state and local public services for maternal health, made possible by the provisions of the Social Security Act. The American Committee on Maternal Welfare, Incorporated, with its component organizations, and the state and local maternal-welfare committees have done extremely valuable work.

One of the best examples of what a local committee can accomplish is furnished by the recently published report of the Committee on Maternal Welfare of the Philadelphia County Medical Society.\* For ten years, this committee has worked with patience and intelligence to educate physicians, hospital administrators and the laity. It began with a critical study of maternal death and subsequently extended the study to include stillbirths and neonatal deaths. It early perceived the need for supervision of the work of courtesy staff members and secured the adoption by most hospitals of uniform regulations governing such work. It formulated and adopted a standard governing the admission of toxic patients for hospital treatment. It has induced nearly half the hospitals to provide class instruction in the essentials of good prenatal care and has even provided series of talks for prospective fathers. It has a subcommittee working on the problem of securing uniformity in obstetric hospital records and in reports of obstetric results. Most significant of all perhaps, it has induced nearly all the Philadelphia hospitals with maternity departments to hold regular staff conferences, to which courtesy members are invited, for the open discussion of maternal deaths, stillbirths and neonatal deaths. All this has resulted in a lowering of the maternal mortality rate in Philadelphia from 7.3 and 7.5 per 1000 live births in 1931 and 1932, respectively, to 2.4 in 1940.

It is instructive to calculate the diminution in the total number of deaths that results in this lowering of the mortality rate. From 1932 to 1940, inclusive, there were 1263 obstetric deaths in Philadelphia. Had the maternal mortality rate

\*Maternal mortality: Philadelphia, 1931-1940. Report of the Committee on Maternal Welfare, Philadelphia County Medical Society. *Weekly Report and Medical Digest* (November 22, 1941).

remained at the 1932 level, 7.5, the total deaths in the ensuing nine years would have been 2037. This is a significant and gratifying drop in maternal mortality, and the Committee on Maternal Welfare in Philadelphia deserves a large share of the credit for it.

### CASEY WOOD (1856—1942) AND AMERICAN MEDICINE

THE death of Casey A. Wood, in California, January 26, 1942, brings to an end one of the most remarkable and indeed unique careers in American medicine. Trained on the Continent and in England as an ophthalmologist, Wood became one of the best known students of diseases of the eye in this country. From 1890, when he first went to Chicago to practice, until he retired in 1917, his name was probably more familiar to both ophthalmologists and physicians in general than that of any other man in his special field. He wrote books; edited systems and encyclopedias, served as editor of three successive journals between 1894 and 1914, the *Annals of Ophthalmology*, the *Ophthalmic Record* and the *American Journal of Ophthalmology*; and corresponded with practically every prominent man in his branch of medicine both in this country and abroad.

Wood began his life in Wellington, Ontario, Canada, November 21, 1856, the son of American parents. After an early training in English and French schools in Canada, he went to Bishop's College in Montreal where he received his M.D. in 1877. McGill University also granted him an M.D. in 1906 and made him LL.D. in 1921. Wood became a student at the New York Eye and Ear Infirmary in 1886 and then spent a number of years at the University of Berlin and in various London hospitals, "Moorfield," Middlesex and others. When he settled in Chicago in 1890 (his first book was published in Detroit in 1891), he was one of the best trained men in his profession in America. He soon rose to teaching positions to the professorship of ophthalmology in both Northwestern University and the University of

Illinois. From 1917 to 1919, he served in the Medical Corps of the U. S. Army, ending his service on the staff of the Surgeon General in Washington as a Lt. Colonel, M.C., and was retired with the rank of Colonel in the Medical Reserve.

The historical side of medicine always interested Casey Wood. He began to collect books even before his Chicago days, became associated with Dr. Mortimer Frank, Dr. Arnold C. Klebs and other historically minded physicians and, in 1902, exhibited at the annual meeting of the American Medical Association examples of British and American ophthalmic literature, with the aid of Dr. Harry Friedenwald, of Baltimore, Dr. A. A. Hubbell, of Buffalo, and Dr. A. R. Baker, of Cleveland. The four men had enough books, privately owned, to make the unusual exhibit possible, and Wood wrote up the story in the November 8 and 15, 1902, issues of the *Journal of the American Medical Association*. From then on, hardly a day passed without some progress in his study of the history of ophthalmology. Numerous trips to Europe, three years in India and Ceylon and many trips to the West Indies served his purpose, and especially during the last few years, he was a constant seeker of manuscripts in European libraries, having digested all the printed books he could find on the subject. Making his headquarters in Rome, he sent out scouts in all directions, copying, photographing or collecting the intricate medieval handwritten material in Latin, Hebrew, Arabic and Greek. It was an exacting task, requiring a skilled mind, but Wood made himself as much at home in this scholarly field as he had in ophthalmology itself.

The present war dealt him a severe blow. When the writer of this note saw him in August, 1939, in Geneva, the forewarnings of conflict had already closed many libraries to him, and a distracted man looked out on a crumbling world. He was not immediately beaten, however, for he escaped to America to live in his native country, of which he was so fond, for the last two years of his life.

His most important historical work was the translation of *De Oculis* (Stanford University, 1929), by

Benevenutus Grassus, and he will long be remembered for his charming selection, with Dr. F. H. Garrison, of the poems in *A Physician's Anthology* (London, 1920).

Wood was also somewhat of a zoologist, and in his travels in India and Ceylon, and in British Guiana with William Beebe, he studied the ophthalmology of birds. When about sixty, he published his important book, *Fundus Oculi of Birds* (Chicago, 1917). After many years of labor, he compiled and edited *An Introduction to the Literature of Vertebrate Zoology* (London, 1931), based on the books in the various libraries at McGill University. A library, devoted to ornithology, he gave to McGill in honor of his wife.

Thus passes an American physician, a distinguished scholar, a friend to Canada and a man whose influence, widely felt in his time, will continue in the inspiration he gave so generously to others.

## MEDICAL EPONYM

### VON PIRQUET REACTION

Clemens F. von Pirquet (1874-1929) described "Tuberkulindiagnose durch cutane Impfung [Tuberculin Diagnosis by Means of Cutaneous Inoculation]" before the Berlin Medical Society on May 8, 1907, and his remarks were reported in the *Berliner klinische Wochenschrift* (44:644, 1907). A portion of the translation follows:

If a tuberculous child is inoculated with tuberculin, there appears at the site of the inoculation a small papule that is bright red at first, gradually becomes dark red, and fades out within a week. . . . Nearly all cases of clinical tuberculosis in children give a positive reaction. . . . With increasing age, the reaction becomes more and more frequent, so that among adults nearly all patients show this reaction.

### COMMITTEE ON MATERNAL WELFARE

#### CASE HISTORY: ACUTE INVERSION OF THE UTERUS RESULTING IN FATAL HEMORRHAGE

A thirty-year-old woman in her second pregnancy, which had been entirely uncomplicated and adequately supervised, was delivered at term by breech extraction of a living child. The past

history was irrelevant: the first pregnancy was normal, and there had been no serious illnesses or surgical operations. Following the birth of the baby, the placenta did not separate immediately, and Credé's method was resorted to; the uterus became inverted. The bleeding from this inversion was tremendous, and attempts to reinvert the uterus were unsuccessful. A tourniquet was placed about the inverted portion to control hemorrhage, but in spite of this and a transfusion of 750 cc. of whole blood, the patient died from hemorrhage and shock.

*Comment.* Such deaths must be considered avoidable. When a uterus inverts during attempt to deliver the placenta by fundal pressure, it is natural to suppose that the manipulation is the cause of inversion; certainly, such inversion is not spontaneous. This patient was under the care of a general practitioner, who sought the assistance of a surgeon when the inversion occurred. The bleeding was tremendous, and by the time the consultant arrived the internal os had so shut down on the inverted fundus that replacement under an anesthetic could not readily be accomplished. Practically every inverted uterus can be immediately replaced with a patient under full anesthesia and when it is so replaced, packing of the uterus to stimulate contraction and control further bleeding is indicated. Manipulation cannot effect replacement in some cases, and laparotomy is indicated. The use of a tourniquet to control hemorrhage in a case of inversion is evidence of failure.

It has been noted in these columns that chronic inversion of the uterus occasionally results from an acute inversion, and there is at least one case in which a uterus has been chronically inverted for several months and after replacement has functioned normally, with delivery of a full-term child.

All patients who bleed should, of course, be transfused, and the transfusion should be given before the patient is in extremis.

### DEATHS

EATON — CHARLES A. EATON, M.D., formerly of Boston, died recently. He was in his sixty-fifth year.

Born in Winchester, New Hampshire, Dr. Eaton received his degree from Boston University School of Medicine in 1908. He was a former member of the Massachusetts Medical Society and the American Medical Association.

His widow and two sisters survive him.

McGUINNESS — JOHN F. McGUINNESS, M.D., of Woburn, died June 17. He was in his fiftieth year.

Born in Brighton, Dr. McGuinness received his degree from Middlesex University School of Medicine in 1922. He was a member of the Massachusetts Medical Society and the American Medical Association.

His widow and two daughters survive him.

## WAR ACTIVITIES

## CIVILIAN DEFENSE

## NEW APPOINTMENTS

New appointments for two members of the Executive Committee of the Medical Division, Massachusetts Committee on Public Safety, have recently been announced.

Dr A William Reggio, deputy medical director of the Medical Division, has been commissioned as a major in the United States Public Health Service and will devote the majority of his time to perfecting the organization of the Medical Division for the care of injured civilians in the Commonwealth.

Mr Oliver G Pratt, superintendent of the Salem Hospital and also a deputy medical director of the Medical Division, has been made a consultant in the United States Public Health Service and has been appointed State Hospital Officer, whose duties comprise the organization of hospitals for civilian defense activities. These include blood banks, the establishment of emergency and big hospitals and an accounting to the Government for the cost of hospitalization of civilian casualties. A ruling having been recently made in Washington that civilians injured by bombing or sabotage or during an official blackout may receive federal assistance for hospital care at the rate of \$375 a day.

## MISCELLANY

RESUME OF COMMUNICABLE DISEASES  
IN MASSACHUSETTS FOR MAY 1942

DISEASES	MAY 1942	MAY 1941	FIVE YEAR AVERAGE*
Anterior poliomyelitis	2	0	0
Chicken pox	17	17	1187
Diphtheria	18	9	34
Dog bite	1387	1359	12.4
Dysentery bacillary	5	7	234
German measles	2440	740	368
Gonorrhea	321	319	34.9
Measles	5326	4118	10
Meningitis meningococcal	20	8	79
Meningitis other forms	10	—	—
Mumps	2018	14.9	965
Paratyphoid infections	3	23	372
Pneumonia lobar	211	210	545
Scarlet fever	1128	873	491
Syphilis	573	437	267
Tuberculosis pulmonary	362	303	25
Tuberculosis other forms	23	30	6
Typhoid fever	1	12	5
Undulant fever	971	1157	649
Whooping cough			

\*Based on figures for preceding five years

## GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Anterior poliomyelitis was reported from Chelsea, 1, Lowell, 1, total, 2.  
Diphtheria was reported from Boston, 1, Canton, 2, Fall River, 4, Hampden, 2, Lowell, 1, Millbury, 1, Somerville, 3, Springfield, 2, Winthrop, 1, Wrentham, 1, total, 18.  
Dysentery, bacillary, was reported from Boston, 1, Melrose, 1, Waltham, 3, total, 5.  
Encephalitis, infectious, was reported from Bridgewater, 1, Cambridge, 1, Fort Devens, 1, Quincy, 1, total, 4.  
Meningitis, meningococcal, was reported from Agawam, 1, Boston, 5, Carver, 1, Chelsea, 2, Leominster, 4, Lynn, 2, Newton, 1, Salem, 1, Townsend, 1, Uxbridge, 1, Weymouth, 1, total, 20.  
Meningitis, other forms, was reported from Boston, 1, Cambridge, 1, Chicopee, 1, total, 3.

Nauck, 1, Peabody, 1, Salem, 1, Somerville, 1, Springfield, 1, total, 10.

Paratyphoid infections were reported from Melrose, 1, Quincy, 2, total, 3.

Sepic sore throat was reported from Amesbury, 1, Arlington, 1, Barre, 2, Belmont, 1, Boston, 2, Brookline, 2, Cambridge, 1, Medford, 3, Winchester, 1, Winthrop, 2, total, 16.

Tetanus was reported from East Brookfield, 1, Nauck, 1, Newton, 1, total, 3.

Trichoma was reported from Quincy, 1, total, 1.

Trichinosis was reported from Amherst, 1, Canis, Edwards, 1, Trunton, 1, total, 3.

Typhoid fever was reported from Fitchburg, 1, Randolph, 1, total, 2.

Undulant fever was reported from Waltham, 1, total, 1.

Chicken pox for the second consecutive month reached figures of record high incidence. Mumps again is at a record high level for the ninth month of the past ten months.

Reported at figures above their five year average incidences were anterior poliomyelitis, chicken pox, diphtheria, dog bite, German measles, measles meningococcal meningitis scarlet fever, syphilis, pulmonary tuberculosis and whooping cough.

Bacillary dysentery, gonorrhea, paratyphoid infections, lobar pneumonia, tuberculosis, other forms, typhoid and undulant fever were all reported at figures below their five year averages.

One case of animal rabies was reported from Norwell, possibly the start of a new focus in this area.

## NOTES

Tufts College Medical School recently announced the following promotions on the faculty. Dr James M. Baty, professor of pediatrics, Dr Francis C. McDonald, clinical professor of pediatrics, Dr Richard Wagner, assistant professor of pediatrics, Dr Bernard Appel, assistant professor of dermatology, Dr Francis P. McCarthy, lecturer in dermatology, and Dr Harry M. Powers, associate professor of biochemistry.

Dr Elmer W. Barron has been made professor emeritus of pediatrics. He has been head of that department since 1929 and has taught at the medical school since 1910.

Dr Philip D. Woodbridge, a former member of the staffs of the Lahey Clinic and Boston Consumptives and Boston City hospitals, was recently appointed professor of anesthesiology at Temple University School of Medicine, Philadelphia.

## REPORTS OF MEETINGS

## GREATER BOSTON MEDICAL SOCIETY

A regular meeting of the Greater Boston Medical Society was held at the Beth Israel Hospital on February 3. Dr Harry Goldblatt spoke on "The Humoral Mechanism in Hypertension."

It is agreed that in hypertension there are increased cardiac output, blood volume and blood viscosity, but these do not appear to be initiating factors. The basic cause now appears to be an increased peripheral vascular resistance, which may be on a neurogenic or circulatory basis. Organic blood vessel disease is rarely widespread enough to be a cause. Vasospasm—at least when re-

ficient cause for hypertension, and is probably not neurogenic.

That a humoral mechanism is involved in hypertension is now fairly generally accepted, but the manner of its working is still debated. The finding of an initiating cause is now a major problem. Endocrine studies, particularly on the androgens, originally occupied a prominent role, but are now of questionable value. Surgery, performed on that basis, except in cases of tumors, is also of doubtful benefit. The hypophysis has been intensively studied and has even been irradiated for relief of hypertension. The value of such treatment has not been proved. Renal hypertension was formerly believed to occur only in the presence of recognizable kidney disease with impaired renal function. Innumerable attempts were made to prove a renal basis for hypertension before Dr. Goldblatt employed partial clamping of a renal artery. Even this method had been tried before, but not enough time was allowed to elapse before the results were evaluated. *Incidentally, arterial occlusion does not result in true ischemia but causes a "hemodynamic disturbance."*

In experimental hypertension in dogs, which is similar to the essential form in man, there is no impaired renal function. There is a moderate increase in heart weight, but no true *cor bovinum*. The changes in the vascular tree consist largely in increases in the media. There are none of the intimal changes of arteriosclerosis, which does not naturally occur in dogs. Decreased renal function can be brought about, however, by excessive occlusion of the renal artery, and such a decrease results in profound vascular changes. Although this happens practically overnight experimentally, the resultant condition closely simulates malignant hypertension in human beings. Vascular changes may be caused only by excessive clamping of the renal artery and the other ureter, with a decrease in kidney function. At autopsy, 98 per cent of those with renal arteriolar disease have hypertension.

The lack of a neurogenic element in this form of experimental hypertension was borne out by denervation of the kidneys and removal of the celiac and splanchnic ganglia; there was no effect on the onset of hypertension when the renal artery was clamped. This does not necessarily invalidate the clinical observations on the benefits of such forms of surgery in human beings, whose kidneys present many small "clamps," and there may be a beneficial increase of blood flow. That some substance from the kidney is involved in the phenomenon is proved by removal of the kidney, by the return of the blood pressure to normal on removal of the clamp or of the kidney to which the clamped vessel leads, by the elevation of blood pressure when the kidney is transplanted and the artery clamped, by the elevation of blood pressure when a so-called "ischemic kidney" is transplanted and perfused, and by the failure of the blood pressure to rise when the renal veins are ligated.

The presence of renin in hypertensive kidneys was postulated many years ago, but Landis was the first to establish its true pressor nature by demonstrating the lack of skin-temperature changes accompanying the hypertension. Houssay showed that blood from ischemic kidneys was more vasoconstrictor than that from normal organs, whereas Freedman et al. demonstrated the need for a substrate found in normal plasma in addition to this renal material. Houssay and Page believe that renin is an enzyme or enzymelike substance that reacts with prehypertensin, which is probably a pseudoglobulin with no pressor action, to produce hypertensin (angiotonin), which may be a polypeptide. Injection of hypertensin causes vasoconstriction and hypertension.

To investigate further the relations of the endocrines, hypophysectomy was carried out, and no effect was noted on the hypertension of the Goldblatt kidney. The removal of one adrenal gland and the medullary portion of the other also failed to inhibit the pressor action, indicating lack of control by the medulla. When both adrenal glands were removed, the blood pressure remained unchanged so long as no substitute therapy was administered, but any small amount of remaining cortex allowed hypertension to occur. The prehypertensin titer falls sharply under such circumstances, but this is prevented by the use of desoxycorticosterone acetate. This indicates that the latter substance acts directly on the plasma part of the humoral mechanism. Liver poisoning with chloroform causes a marked decrease in the prehypertensin level even when desoxycorticosterone is administered to rule out its effect on the adrenal cortex.

The treatment of hypertension depends on the cause of the particular case. That associated with unilateral renal disease may be materially benefited by *nephrectomy*. Increase of the accessory renal circulation through the spleen or other organs has shown some promise in dogs but not, so far, in man. In such dogs, only the renal artery is involved, whereas there is intrarenal disease in human hypertension. Medical treatment, except for fleeting relief from the nitrites, is unavailing. Many attempts are being made to use various tissue extracts. Hypertensinase, or angiotonin inhibitor, obtainable from many tissues but especially the kidney, has given rise to some alleged good results in animals and man. Wakelin has attempted to desensitize against renin by gradually increasing the amounts injected. But the antipressor titer is the same at the high and low levels of blood pressure. In all these attempts with tissue therapy, the question of the purity of the extract arises, for in most cases there are large amounts of both renin and inhibiting substances. The importance of the patient's temperature cannot be too strongly stressed, for those who respond invariably had some fever. Fever therapy with typhoid injections accomplished the same ends in reducing hypertension. The possibility of a nonspecific protein reaction therefore arises.

The discussion was inaugurated by Dr. Robert W. Wilkins, who reported on the crucial experiment of administering potent angiotonin to human volunteers. There was a resultant hypertension and vasoconstriction, but certain side reactions not characteristic of essential hypertension occurred. The most significant of these was an almost constant rise of venous pressure to heart-failure levels. The second contribution concerned the return of blood pressure toward or to normal on removal of a responsible diseased kidney. Therefore, hypertension is not necessarily a response to vascular disease and is not required to drive the blood through narrowed vessels, as was formerly taught. The changes, then, are not always irreversible.

Dr. Mark Altschule emphasized the presence of an increased venous pressure in most experimentally hypertensive animals as compared with diseased human beings, and therefore questioned the similarity of causation. Dr. David Ayman stated that the present surgical treatment of hypertension does not increase the renal blood flow, as demonstrated experimentally.

Dr. Lewis Dexter, in discussing the relation of the adrenal glands to this subject, stated that adrenalectomy results in a decrease of precursor in only about 50 per cent of the dogs. Evaluation of renal extracts reveals that many of them used therapeutically contain variable amounts of, or no, renin and hypertensinase. One form of therapy is to attempt the destruction of renin or hypertensin, but so

no effective material has been found. A renin inhibitor may exist but is still unknown. Hypertensinase is as yet not a definite entity, for there are many reactions from this impure, labile substance. Finally, a transfer in toto of the humoral mechanism of experimental animals to man is dangerous, for the causes of hypertension in man are variable and complicated.

In conclusion, Dr Goldblatt offered impurity of the extracts as the explanation of the elevated venous pressure observed by Wilkins. He agrees with Dr Altschule that the high-powered character of hypertensive patients is a result rather than a cause of the elevated blood pressure. However, there is a large percentage of hypertension in the sluggish Negroes of the Virgin Islands. So far as the amount of blood flow following surgery on the abdominal sympathetic ganglia concerned, he believes that clearance methods are not sufficiently accurate even in the hands of their originators. That so-called unilateral renal disease may actually be bilateral is possible on the basis that hypertension may be present even in the absence of decreased kidney function. At present there is no means of determining the hypertensive state of a kidney by the common functional tests.

## BOSTON ORTHOPEDIC CLUB

At a regular monthly meeting of the Boston Orthopedic Club held at the Boston Medical Library on February 16 Dr Charles Bradford spoke on Recent Experiences in England.

The first part of the discussion concerned the problems encountered at a base hospital about 50 miles from London where there are 1700 beds, of which 300 are for orthopedic use and 100 for convalescent patients. Injured persons arrive one to three days after an injury in the city by automobile and come in groups of 20 to 200 at one time. On admission they may be suffering from fatigue or may be in actual or incipient shock, but very few deaths result. However about 30 to 45 per cent of those injured in raids die largely from primary shock or blast, or both. Once that phase has been surmounted, the results are good, probably because of the more intelligent treatment of shock. Sixty to 75 per cent of the movable cases are orthopedic.

The primary treatment at the site of the raid is usually inadequate because of the character of the incidents and the overcrowding of the stations. Debridement, although attempted, is often hurried and incomplete and such wounds should, therefore be left open. This should not be considered analogous to compound wounds of civilian life, in which careful thorough preparation allows primary closure. Chemotherapy with the sulfonamides is invariably employed, but it is difficult to evaluate the results, for there is no correlation of amount of drug, degree and quality of debridement, amount of contamination and so forth. The tendency to place too much reliance on chemotherapy at the expense of thorough mechanical cleansing is a definite hazard. At least 50 per cent of the patients reach base hospitals infected because of inadequate debridement or faulty use of chemotherapy, or both. The proper use of the sulfonamides however probably does lengthen from six to eight to fourteen to twenty-four hours the period in which primary closure of wounds is possible.

The choice of methods of immobilization is still being debated. For a fracture of the femur there seems to be no question about the value of the Thomas splint. For fractures elsewhere, the plaster method of Orr is most popular. The splinting is more adequate than any other

method the soft tissues are protected, and a certain control of the spread of toxins is accomplished. Its foremost advantage however, is the prevention of needless tampering with the wound. Among its disadvantages is the need for ceaseless observation and intelligent care to guard against the development of pressure sores and other sequelae of edema for which no precautions are taken in application of the plaster. Little, if any, progress is being made in the treatment of shock in England as compared with that in the United States. There have been difficulties with plasma precipitation and serum is therefore being more widely used. American plasma is apparently superior and the organization for transportation and so forth in England is excellent.

In the treatment of the later stages of fractures, most of the older men favor the Orr method, for they appreciate the greater comfort to the patient as compared with the multiple dressings of the last war. The wounds look as well if not better and the clinical course is usually much improved. Amputations have been performed less frequently but chemotherapy may have had some effect on these statistics. The bacteria encountered have been largely staphylococci anaerobic and aerobic streptococci and *Clostridium welchii* but the incidence of gas gangrene has been only 0.5 per cent. This may also have decreased the number of amputations. The value of the Orr method in decreasing secondary contamination of wounds has been amply borne out by studies on the flora of wounds on surgical wards. In this way it has been demonstrated that most infections are contracted in the wards rather than being latent in the wounds. With the Orr method the opportunities for cross infections on a ward are greatly decreased.

There are the usual late complications encountered in civilian orthopedic practice but there is definitely a higher incidence of infection. Wounds on the whole are multiple. In England, plating of fractures is in great disfavor because of numerous failures which are attributable to inadequate sepsis and small plates and screws that pierce only one cortex. But in an attempt to rehabilitate quickly, especially in the air corps, this conservatism has given way to radicalism in the form of an extravagant use of bone grafts (Watson Jones). It is often impossible to plate or graft a fracture, and here the Roger Anderson or some similar apparatus has a large scope. In 65 cases in which this splint was employed there were no failures, and there was a wide applicability. There is need of much technical study, skill and constant care to prevent failures however. One excellent feature is the opportunity for making patients ambulatory in a short time, and for transporting fractured femurs and patients with multiple fractures. When there are widespread wounded men in remote places a trained surgeon and an assistant can obtain immobilization with this apparatus without the necessity for x-ray examinations and the patients may then be transported to base hospitals in safety and comfort.

The problems in a bombed city itself are numerous. To relieve the hospitals of the large number of cases, it is necessary to have well trained first aid parties, preferably under the direction of a local physician. Such groups decide whether the slightly injured may return home or should be sent to first aid centers, which are not in hospitals but are easily accessible and are under the jurisdiction of competent doctors and nurses. The practical application of first aid technique is taught is often faulty and such things as sepsis naturally are useless in the streets during a blackout. The amount of first-aid treatment at the spot has been found to impede hospital administration.

tion and is accordingly confined to the control of major hemorrhage and the splinting of obvious fractures, with especial care of suspected spinal injuries.

When one attempts to treat severely wounded persons in the midst of a "blitzed" city, the available hospitals are merely used to best advantage. They are protected physically by sandbags, fire watchers and so forth, but some damage still occurs. Casualty rooms should be on the ground or preferably a basement level. Co-ordination must be of two kinds: interhospital and intrahospital. When most of the damage occurs in one part of a city, it is imperative not to overload the physical and personnel facilities of the neighboring institutions. For this purpose of interhospital co-ordination, a center is advisable, but this is so far not being well carried out in England. In a given hospital, the number of admissions is entirely unpredictable, and the staff must respond immediately and improvise whenever necessary. Three important groups should be organized: that for admission, in which competent clinical judgment is necessary; that for the treatment of shock, which can function in any large space equipped with many beds, blankets and intravenous fluids; and surgical operating teams, which should have two or three tables in one room rather than a similar number of rooms. The proper choice and administration of anesthesia cannot be too strongly emphasized. A good supervisor can control a large group if the cases are well arranged. Nitrous oxide is probably greatly underrated, and Pentothal sodium has been found excellent, especially in shock. At Pearl Harbor, a large amount of drop ether was administered, and this method is strongly advocated as being easiest, if not safest, especially in the hands of untrained anesthetists.

In conclusion, the role of the fire and public utilities departments as a first line of defense was emphasized.

**Dr. Ernest P. Boas, M.D.**

## BOOK REVIEWS

*Treatment of the Patient Past Fifty.* By Ernst P. Boas, M.D. 8°, cloth, 324 pp., with 19 illustrations. Chicago: The Year Book Publishers, Inc., 1941. \$4.00.

Pediatrics and public-health education, by extending the average duration of life, have made geriatrics a very important department of medicine, and Dr. Boas has drawn on his wide practical experience and extensive study in this field to write a book notable for thoroughness and clarity. He defines senescence by indicating the factors that, singly or in combination, produce the condition, and the section devoted to cardiovascular diseases, which constitutes more than one third of the book, should be of great value to the general practitioner, who is usually the first to encounter the symptoms of physical or psychologic degeneration. Although fifty is taken as a dividing line, one must avoid being arbitrary in this matter, since there are persons in whom warning signals are evident earlier, and many others with healthy bodies and happy minds who are free from such symptoms until a much later period.

The author has given excellent advice on the aftercare of patients with coronary-artery involvement, as well as a pertinent explanation of the relation between these diseases and diabetes mellitus, with a wise warning against the use of insulin in such cases.

Of equal significance is the chapter on diseases of the lungs, which stresses the effect of such conditions on the heart and circulation. It is surprising, however, that more attention has not been directed to some of the blood diseases occurring in the middle years.

Since medical or surgical treatment has less of permanent success in the elderly, serenity and comfort become prime objectives; and when, as sometimes happens, old age is more a state of mind than of physical degeneration, the treatment is correspondingly advantageous; however, in the majority of conditions, Dr. Boas might well have indicated more fully the definite treatment in these situations.

The book offers nothing that is new to specialists in various fields, and is primarily a general textbook of medicine, with emphasis on diseases occurring due to senescence.

*Infant Nutrition: A textbook of infant feeding for students and practitioners of medicine.* By William McK. Marriott, M.D. Revised by P. C. Jeans, M.D. Third edition, cloth, 475 pp., with 31 illustrations. St. Louis: The C. Mosby Company, 1941. \$5.50.

Dr. Marriott's book first came out eleven or twelve years ago with the avowed purpose of presenting the infant nutrition on a relatively simple, yet scientific, basis. It did that, or helped to do it. No pediatricians used Marriott's method for the various ways of feeding babies, — as doubtless there always will be, — any of which may be successful so long as it is adherence to certain underlying principles were emphasized, and still is. Dr. Jeans has not altered the general structure of the volume, but merely brought in factors that keep the subject thoroughly up to date.

To the specialist in pediatrics, all this ought to be familiar ground of course, but to the general practitioner, to the student in medical school, it will be a most useful text. The viewpoint is neither too narrow nor too broad, and the book is well recommended.

*Health Resorts of the U. S. S. R.: A symposium of articles.* Compiled from data of the Central Institute of Balneology in Moscow. Editor: Dr. I. A. Pertsov. 8°, cloth, 270 pp., with 45 illustrations. Moscow, Russia: The U. S. S. R. Society of Cultural Relations with Foreign Countries (V. O. K. S.).

This is a comprehensive work on the health resorts of Russia, which abounds in innumerable mineral springs, deposits of medicinal muds. At present, many of these places in the Soviet Union possess natural curative agencies covering all known types of caliche mineral waters. The vast territory of the nation has diverse climates: humid, subtropical, arid, subarid and mountainous. Stalin Five-Year Plan included the reconstruction of existing health resorts and the building of new retreats for the benefit of the people.

*The Premature Infant: Its medical and nursing care.* Julius H. Hess, M.D., and Evelyn C. Lundeen, R.N. cloth, 309 pp., with 74 illustrations. Philadelphia: J. Lippincott Company, 1941. \$3.50.

This is by far the most complete and satisfactory treatment on the premature infant that has ever come to the attention of the reviewer, and every physician and every nurse charged with the care of such infants would do well to have the volume at hand. It is specific down to the minutiae of procedure, and scarcely a question that arises in this field is not anticipated. A mere glance at the well-chosen illustrations often shows exactly how that should be done.
